I am using the Distance to Fault mode. I've tried several frequencies
for X=0, and sometimes get the 26.6 foot figure, other times
non-sensical answers in the thousands of feet.

Hello everybody,

I hope everyone had a very Happy Easter. I have a spare 2:1 current balun and would like to use it to feed a vertically oriented single-band full-wave loop. I began to wonder; Can one feed two vertically oriented full-wave loops perpendicular to each other with a common feed point? Any opinions? Thanks in advance. As always, take care es...

You can easily excite a common mode wave on coax with a TDR -- or transmitter -- simply by connecting to it with pigtails. This provides a path between the inside and outside of the shield, unlike a proper coax connector which preserves the integrity of the shield.

Hello Bert,

When you have identical loops, with same orientation, and distance between them is less then 0.2 lambda, you can connect them in parallel. Current in both loops will be the same (magnitude and phase) and far field radiation pattern will also not change (with respect to a single loop).

When the distance between the loops >> wire diameter, you will experience an increase in useful bandwidth. Impedance at current nodes will not change that much, but impedance at voltage nodes will reduce. Due to the mutual coupling, you will experience some drift in resonant frequency.

Feeding in opposite phase will give a complete new radiation pattern, significant reduction in useful bandwidth and possibly reduction in radiation efficiency.

Best regards,

Wim

That's very interesting. The newest online manual has a slightly
different procedure for measuring Distance to Fault. When it stops
raining (and the balanced line dries off) I'll go and measure again
with the newer procedure.

Hi Nico,

You are missing a "Tag" 6, which should connect tags 5 and 7.
On a quick check; tags: 2, 4, "6", and 8 are 10mm long. As close
as possible; all other tags should be segmented in 10mm lengths --
for example tag 1 is 81 mm long and should be segmented as:
GW 1 8 0 0.025 0.919 0 0.025 1 1.e-3.

Your "GE" card shows "no groundplane. It should be changed to:

GE 1 0 0

indicating a ground plane is specified.

If you wish to show the far field you must include and "RP" card;
for example:

RP 0 181 1 1000 -90 90 1.00000 1.00000

Which shows Theta from -90 to 90 degrees at phi = 90 degrees

You should also show an "EN" card at the end of your code to
indicate program end.

Regards,

Frank

I finally got it to work properly. The trick is getting Xs=0 at a
second frequency -- I couldn't get it on the same band as the first
frequency but had to go to a second band, either up or down, and once
the second frequency was found with Xs=0, it came up with the correct
distance to fault, 53.2 feet.

Source record: 10353

I am interested in having a rapid set up multi-band vertical for Field Day and EMCOMM. If I use the Hy-Gain sixty four foot (64') push up mast as the radiator and an ICOM AH-4 as the automatic antenna tuner is this likely to be an effective approach to having a rapid set up multi band vertical? Will I need radials? Should they be elevated or can they lie on the ground? Since the total length of the radiator is less than a 1/4 wave on eighty meters at say 3.6 MHz will that make the antenna ineffective on eighty meters?

Second question would four of those sixty four foot masts make an effective forty meter four square. Yes I realize that it would cost eight hundred dollars for the masts alone before the cost of controller, remote, phasing coax, and control cable. Once again would radials be required for forty meters.

I've only been back in radio for a few years after very long gap so I'm starting over and finding the learning curve a little steeper than I remember.

Side route here, can be skipped to remain strictly on topic.

Ohh, Ohh! I can segue into my radials burying method. Banned in several countries!

Beyond Richard's concise answer, Elevated radials are kind of a PITA, and the stuff that neighborhood Antenna bans are based on. And for this use, they are also going to be in the way.

I'd also note that one method of laying radials is easy, but not so good. I tried laying half of my radials laying the lines on the ground, held in place with ground staples. It works well technically, for practical purposes, not so good.

Raking the yard is a great way to lift the staples and the rake pulls the wires up also.

I'm a big fan of shallow trenching.

Now on to my trenching method......

All those years of organized sports have taught me many things- Sportsmanship, Teamwork, Goal setting and achievement, and especially

how broken bones, pulled tendons, and ligaments can conspire to make
life a little painful as the years go by.

Anyhow, hand digging a trenches and laying the radials is really painful
for me.

And renting a professional trencher just goes against my Hamness, M R
expensive!

The following is a description of a method I have used, and not a
suggestion that anyone actually do this. As they say on Mythbusters,
Don't do this at home - are you crazy? Never use a tool for other than
it's intended purpose. Do not use sharp things - ever. You have been warned.

So my solution is using an inexpensive electric chain saw to do the
trenching with. Simply start at the ground plate of your vertical, and
dig a trence with the chain saw. Works a trick! Lay the radial wires in
and cover them back up.

This is needless to say, rather hard on the chainsaw blade, and probably
the chain bar.

I repeat, don't ever try this method. It's dangerous.

Back on topic

For emergency work, simplicity is mandatory. I see the idea of setting up multiple masts and radials on location as an unneeded complication, and a failure point as well.

I'd also be inclined to have different antennas for each use.

And while it's heresy in here, if you want ease of tuning (or complete lack thereof), you might give some thought to a T2FD folded dipole antenna. Not a particularly great antenna, but wide band, and you make up for it's inefficiency by running legal limit power.

Otherwise give some thought to dipole antennas, perhaps a doublet, and use an autotuner on it. A couple masts, amybe those fiberglass pole types and you should be good.

If you really want directional power on 40 meters, look into a portable mast and a 40 meter beam. Coupled with full legal limit power, you'll make your own propagation!

I think that outside of a permanent EC command center, simple and quick is the order of the day.

> multi band vertical?

Yes..
You don't need that much height, though.. the loss in radiation effectiveness going from 1/4 wavelength (20m long) to 1/8 wavelength (10m) isn't all that big a deal. It's when you get down to the 1/20th wavelength and the feedpoint Z gets very wild that you have problems with loss in the matching network.

Will I need radials? Should they be elevated or
> can they lie on the ground?

Yes.. you do need radials. Laying on the ground is just fine. Get some very flexible stranded insulated wire (the kind with lots of fine strands is better.) and figure a way to rapidly throw it out and store without tangling. I've thought about spring return reels.

3 or 4 makes a huge difference over 1 or 2. after that, it's a bit of diminishing returns.. You'd be better off just doing what the people who do this for a living (rapid deploy HF comms) do.. jack up the Tx power.

BTW, a better approach than a vertical might be a inverted V dipole from the top of your 60 foot pole. MUCH better radiation effectiveness because of H polarization..

Since the total length of the radiator is
> less than a 1/4 wave on eighty meters at say 3.6 MHz will that make
> the antenna ineffective on eighty meters?

Nope.. it's the loss in the tuning network that's the thing to worry about.. you could make a lumped matching network to feed with your autotuner if you're worried..

>

Radials are (almost) always required for verticals. even if you don't install them, your feedline shield will act as a radial with

unpredictable and usually undesirable effects.

Running a 4 square with autotuners at each element is VERY difficult (if not impossible).. the tuner changes the phase shift, and the interaction from the other antennas will screw up the auto adjustment algorithm.

> the top of your 60 foot pole. MUCH better radiation effectiveness
> because of H polarization..

Much easier to deal with. You really don't want to have to deal
with radials at a field day. And using an antenna tuner to match
a vertical is not the greatest way to go about it.
Then you have the radiator height issue.. A 64 foot mast is too
tall for most of the higher HF bands. So it's not going to be too
practical for multi band use unless it's only for the lower bands.
Heck, it's slightly tall even to be a 5/8 wave on 30m...
It's going to be fairly useless as a vertical on 20m and up..
High angle lobes..

If it were me, I'd use the mast to support dipoles for each band
to be used. I feed them all with a single coax and spread the
legs apart at right angles to minimize interaction.
Or one could use a multi band dipole of some type.
One method I used to use camping was the "jumper"
dipole. IE: I'd run a 80m length dipole, but have insulators
breaking it up into higher band dipoles. For 80m, they would
all have jumpers across them.
For higher bands, you would use remove the jumper across the
insulator to shorten the length.
But I prefer the parallel dipoles for FD use, and I almost always
have enough room to do it. That way I have instant band changing
with no retuning, fiddling, etc..
If I were to use a vertical for all bands, I'd probably go with some
type of elevated 1/2 wave design that didn't require radials.
But except for far off DX, I would prefer the dipoles.
The bulk of FD contacts are not going to be DX on the lower
bands. You would be better served with the NVIS pattern of a
dipole on 40, 80 meters. An 80 or 40 meter dipole will work quite
well if supported at 60 ft at the apex. Really doesn't have to be that
high, but if you can get them up to 60 ft, they will work well.
Even to most DX.

1109. HY-Gain Trap Orientation th5mk2

Newsgroup: rec.radio.amateur.antenna
Date: 2010-04-09 01:00:44 UTC
From: Chuck Forsberg WA7KGX N2469R <caf@omen.com>
Message-ID: <CbKdnUPWS-eh4SPWnZ2dnUVZ_hydnZ2d@giganews.com>
Source record: 10359

I am installing a used Hy-Gain th5mk2 tribander.
A previous owner added screws on some of the elements at the
boom to element clamp and between element sections.
This is not mentioned in the manual.

Unfortunately whoever added the screws forgot to make sure
the trap assembly drain holes point down. They are up to
20 or so degrees from straight down. Is this good enough
or would it be better to remove the screws so the traps can
be adjusted with the drain holes down?

1110. Isopole parts

Source record: 10360

I came by the bottom half of an Isopole 2M antenna. I am missing the matching network and upper portion of the antenna. I am looking for information on purchasing or fabricating these parts. I have a home made 5/8 antenna that consist of a SS whip mounted on a Lucite rod that also serves as a form for the matching coil. Would this work? I have my doubts as it would considerably longer than the original.

Jimmie

Hi Chuck,

You could drill drain holes too.

Hi Jimmie,

What band was the whip home made for?

Should work if you can find a way to mount it. The original upper
5/8 whip was 50 inches, same as the lower 5/8 section, not counting
the lower decoupling cone.

A friend of mine planted a bamboo shoot in his side yard, now it is taking over his and his neighbors yards. Told me to cut down all I want. Had planned to use it for bean poles and plant supports, then it occurred to me: quads, moxons, spiderwebs -- this stuff is really strong and stiff. Some canes are 12-16 feet long.

Anybody have experience with bamboo, especially used as semi-permanent end supports for dipoles and inverted vs?

How long did it take to grow to 12 - 16 feet long? That would be great to
use on a hex beam. How flexible is the bamboo?

I used some bamboo for a Flag antenna about 10 years ago, I prepped and
applied an epoxy paint to the bamboo and after 5 years I needed to replace
it.
The next time I used fiberglas pipe I got on Ebay.

Bamboo used to be very commonly used for quad spreaders. I think the practice was to put spar varnish on them to make them last. I'll bet you could get some tips from an old Handbook, say '70s and earlier.

Ive built a few antennas using bamboo including a 5/8th CB antenna
that was up for at least 10 years. All did not do so well. Painting
before the wood had a chance to thoroughly cure was a problem as a
matter of fact it was worse than not painting them at all.

Dunno how long it took to grow, but I'm told you can see growth in a
day's time. Bamboo is some kind of giant grass and comes in hundreds
of varieties. It is fairly stiff for the thickness and weight.

Yeah, I was thinking about a 17-15-12-10 quad, or maybe a Moxon. I'm
too fickle about antennae to worry about them rotting! :-)

Bamboo is making a resurgence. Not only might you find ideas in older books, but newer ones as well. ARRL's 2008 "Simple and Fun Antennas for Hams" details the use of bamboo for a wire antenna. On page 16 of Chapter five, the author recommends using "vinyl electrical tape to secure the wire to bamboo to make antenna elements."

In that article they are using it as a mast in an inverted-L wire antenna. I could imagine using bamboo as spreaders for a folded dipole, or as supports for a yagi or loop and just attaching wire to the bamboo to create elements. Using a saw to create a notch in the end of the bamboo would make it great for running wire across the ends.

I wonder what the maximum support length for a piece of bamboo would be? I would also be interested to see if someone knows of a way to jigsaw the pieces properly and maybe use hose clamps to create sections longer than 12 feet.

-
Yep. Years ago CQ magazine had an article about a $4 2 element 15 meter beam made from bamboo. Of course, bamboo fishing poles were about $0.25 each back then. The boom was made from 2 1x2 wood screwed together, and there were 6 foot long 1x2 boards at each end of the boom for element supports.

Aluminum foil was laid out on the ground and the pole was placed on top and wrapped with the foil. Electrical tape wraps between bamboo joints kept it in place. Electrical connections were via hose clamps on the butt ends of the bamboo poles.

The elements were mounted on the boom/cross supports via screw-in supports intended for routing 300 ohm tv cable. Open the eye of the support, and pop out the cable centering insulator, screw it into the boom end supports, put the element in place and crimp down the eye on the element.

Works great, and doesn't look too bad. However, it may not pass the neighborhood popularity test.

My thought exactly. Maybe some kind of scarf joint or other and hose
clamps. How about multiple (3?) canes with butt/scarf joints
staggered along the length? Dowels maybe?

Bamboo is a good resource. On the other end of the scale I recall that
Post made a good Slide Rule in the 1950's from Bamboo. I still prefer
my Dietzgen though.

I wonder if it could be cultivated in North Carolina?

Hi John,

More's the problem of getting rid of it if it becomes a nuisance.

It probably will if you pick the wrong specie. Bamboo propagates
(imagine, talking about plants and still being "on topic") through
the roots and those roots quickly propagate far and wide. You either
have to put in deep root barriers, or have neighbors that like a
living fence (which might be another problem through CCRs). Bamboo
generally likes wet (read soggy) soil.

I don't know about cultivated, but in the mid part of NC it will grow like
the weed it is. If planted, you may have trouble getting rid of it.

There are two major types of bamboo. Richard's description matches the
running type. The clumping type is not highly invasive and its spread
is easy to control.

According to the Maryland Cooperative Extension Service
- quote -
Bamboo grows best in a fertile, well-drained soil rich in organic
matter.
- end quote -

Half inch diameter schedule 40 PVC tubing might be a better choice for
a framework than bamboo canes. Through the years I have built several
multiband VK-parasols using PVC tubing. The Oct 1984 issue of 73
descibes the VK-parasol and provides the appropriate formulas.

Yes, those were good rules... although they were actually manufactured
by Hemmi in Japan, and imported and sold here in the U.S. by Post.
The Post Versalog 1460 was one of the best (and best-known) of these
high-end 10" rules.

Dietzgen tended to use mahogany, although they did have a bamboo
version of their high-end "microglide" 1734 rule. The Dietzgen rules
were also very nice... if I recall correctly my good high-school
log-log rule was a Dietzgen.

I always thought that if I got really POed at someone I would plant
kudzu and bamboo in their yard.

St. Justin says,
"Human life has the power to decide on
decisions available, choosing right over wrong, truth over
untruth. These Words have been spoken before.
Repetitiveness, as man knows, is the best instructor in
the world."

REVELATION DELIVERED THROUGH FRANCES M. KLUG
ON SEPTEMBER 27,1995 AT 2:27 P.M.

SAINT JUSTIN

" I am Saint Justin. Mankind believes in
Christmas, Easter, and when a New Year begins. These
three things I mention, because in many ways they are
celebrated by men, women and children, and in the
celebration there is always much festivity, and much
concern for the very young and for those close to them.
These days I point out are small in number, and yet
important to mankind because mankind makes them
officially important.

All of Us Here in the Heavens, when We speak,
there is a tremendous desire that mankind begin to feel
the importance of every day in life, because each day
has an importance in it that is above and beyond
celebration. It is important, because for every act, for
every thought, for every deed, for every mood, of each
day, a Soul of the individual will be accountable to
God. To some, this statement will not register in its
full impact, but it is important for mankind to begin to
see each day as being a day of responsibility, and a day
that will be accountable to God for every act that was
performed. It is important for mankind to see human
life as the privilege it is, because human life has a
Goal beyond any other goal.

Men, women and children are told to read scripture,
or some form of prayers drawing their attention to God,
or some particular Saint, or even to someone who they
know who has died.

Materialism is most times of the utmost importance
in mankind's thinking or desire to obtain. Many
grievous sins are committed against one's Soul, because
of the manner in which mankind achieves materialistic

values. Also, from little on, some children are taught that education is the most important thing to their welfare, because through education they will be able to strive for higher places; but what is left out many times, is any conversation regarding what the Real Goal of life should be, and that is Sainthood.

At this time throughout the world, there are many forms of religious beliefs, most of them man-made, because through religion, many times, there can be much financial gain, so when an individual, or individuals, feel they have the knowledge, the ability, the personality, to instruct thousands of others on scripture, on believing in themselves, on the importance of learning to spread God's Words, it is sad to see so much diabolical practices thrive in this manner of so-called spiritual beliefs, practices, encouraging more and more and more to become involved.

At the time Our Lord walked the earth, and much of what He spoke was not heard in distant places, the Words were passed on through crowds, and it was difficult for the exactness to be transmitted, sometimes because of the different dialects, sometimes because of the beliefs that the individuals had, sometimes because there was so much interference. That is what is happening today in your time. There is much misinterpretation, much personal manipulation, and many preaching and teaching, because they want attention and, of course, financial gain.

This Miracle has been given to the world, most of which has been written, so that there can be no misinterpretation, no personal gratification, and so that all people reading the Words, no matter what religion they are, it is to instruct mankind on the Importance of their Soul.

It is sad to say, many times, when The Father hands a Precious Gift to the world, It is abused. All of Us Here in the Heavens constantly do all We are able to do, to protect this Miracle in many ways, in many areas. Sometimes when We see someone, or more than one, not just speak out against this Gift of The Father's Love, not just mistreat It, but who diabolically misinterpret It, it is difficult, because Each Word handed to mankind is like a Diamond of great worth, and for these Diamonds to be abused physically, morally, ungraciously, it is a sadness, because All that is given is beyond human ability to give; and also, if all men who were instructed in sound religious factors, truths,

had been doing what they agreed to do, this Miracle would not have been necessary, but satan has so many devious methods to use, and many times will go to the highest places, to either confuse with his hate, his jealousy, or infuse wrong interpretation with his hate and/or jealousy.

I could speak hours on this subject, because it is a subject that mankind should not reject or resist thinking about. It is important for mankind to look to the value of what a Precious Gift human life is, and to see beyond this value, as having a particular place above all other creations The Father has given. Human life has abilities, mentality. Human life has the power to decide on decisions available, choosing right over wrong, truth over untruth. These Words have been spoken before. Repetitiveness, as man knows, is the best instructor in the world.

As mankind learns to repeatedly learn more about The Father's Commandments, mankind can become a great Saint, because the more one learns, the more one applies the good in what they have learned, there are obviously great benefits. Remember this. So be it."

1143. Wire glue...a possible help for using CATV line for amateur applications??

Newsgroup: rec.radio.amateur.antenna
Date: 2010-04-12 02:56:43 UTC
From: Dave Smirkenberg <smirk50@rocketmail.com>
Message-ID: <4abc0e55-e669-4249-a1f5-6914d40973da@g11g2000yqe.googlegroups.com>
Source record: 10393

I bought a small jar of a carbon based adhesive called Wire glue on ebay last month. Thought it might be good for PC board projects where you have to solder in really tight spots.

Today while putzing in my attic I came across a roll of about 200 ft of 75 ohm CATV cable that I stashed there when I moved in back in 2002. Well, the reason I never used it for anything in the first place was the hassle involved in attaching reducing adapter like a UG/176-U to the aluminum foil shield. It hit me that this "wire glue" might be a decent way of doing so.

Has anyone had any experience with this stuff? If you are not familiar with the material all you have to do is search for "wire glue" on ebay. I'm curious as to the opinions of many of our esteemed group members.

Thanks,

Dave

>Richard Clark, KB7QHC

Agreed. K&E was the best. Part of my collection:
<http://802.11junk.com/jeffl/pics/slide-rule/slides/slide-rule.html>
The yellow slide rule is an aluminum Pickett and Echel "Synchro
Scale". The lower K&E is mahogany laminate.

I never really liked the bamboo or mahogany slide rules. I don't
recall the problem, but when I eventually tried an all plastic K&E, I
declared it the winner. I also couldn't get use to the circular
variety, mostly because it didn't fit in my pocket.

<http://www.sliderule.ca>

I've never built a quad antenna, but my uninformed and never humble
opinion is that fiberglass rod or tubing looks like the best:
<http://www.mgs4u.com/fiberglass-cubical-quad-spreaders.htm>
<http://www.mgs4u.com/fiberglass-tube-rod.htm>
However, if the bamboo is free, then it's a very suitable 2nd best.

If the cable is RG-59/u, consider leaving it in the attic until it
rots. If it's RG-6/u, it can be used for ham radio purposes. Instead
of the proposed UG-176/u to PL-259 adapter kludge, just install the
correct compression type F connector on the ends of the RG-6/u and use
adapters to go to PL-259 or whatever. You'll find that the 75 to 50
ohm mismatch loss is rather minimal.
<http://www.qsl.net/n9zia/wireless/75_ohm_hardline.html>

As for the wire glue, due to the lack of a suitable manufacturer and
part number that can be researched, my guess(tm) is that it's much
like "metallic epoxy", which is nothing more than aluminum or graphite
powder mixed into the epoxy. The particles are quite far apart from
each other, resulting in extremely poor conductivity. Since RF likes
to flow on the surface of conductors, such glues are going to have a
fairly high surface resistance, and are therefore useless for RF.

1149. Magnetic Loop Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2010-04-12 21:03:25 UTC
From: Irv Finkleman <finkirv@shaw.ca>
Message-ID: <sULwn.133112$Ye4.65386@newsfe11.iad>
Source record: 10399

I am in the process of building a magnetic loop antenna. I have a roll of 1/2 inch
flexible copper tubing. I would like to increase the effective tubing size by silver
soldering a second loop of equal size to the first loop -- point for point. Would
it make any substantial difference if I just tacked the two together at a number
of points, say every 45 degrees or so, or would it be better to solder them
together through the entire circumference?

The loop will be run HF QRP, with a maximum power of five watts,

Thanks in advance for any advice on this matter.

If you're careful to keep them nearly exactly the same length (that is,
put them side by side rather than one inside the other), I think you'll
get by ok by soldering in a few places. I recommend including soldering
at the ends, or near where you make feed or loading component connections.

Having used, and had grief from, the best quality silver and gold conductive epoxies, I'm highly skeptical of this stuff except in the very least demanding of applications. It appears to provide no physical strength to the joint, so any connection would have to be physically strong to begin with -- in which case you've probably already got decent electrical contact and just need to keep air and moisture out of the joint. I'd be surprised if flexing, temperature changes, and any other disturbances didn't cause the already marginal resistance to increase, possibly dramatically. It looks to me like attaching a reducing adapter is very likely to be much less of a hassle in the long run than fooling with this stuff.

Have you considered putting an F or BNC connector on it, then using an adapter as necessary?

Hello Irv,

As Roy also said, when they have the same size (diameter, shape and
length), some points are sufficient (electrically soldering just the
ends is sufficient). Limit the number soldering points to what is
good for mechanical stability.

Use copper or plastic mounting hardware. Resistive materials (steel,
stainless, etc) that are in the field (close to the copper tubing)
reduce efficiency.

Best regards and let your waves hit the sky,

Golly, I hope you didn't hurt yourself going through so much trouble to
be so informative.

I'm certain he now has a much better understanding of phasing and
impedance matching after that exhaustive explanation from such an
obvious bastion of knowledge & information.

Hello Wim,

I was getting the idea he wants to have two full wave loops in parallel
at the feedpoint, one ascending from the lower corner and one decending
from that point but oriented off by 90° in order to make an omni.

I've also wondered about that design. Have you tried this arrangement,
and if so, what feed point impedance did you have?

I am taking your question as, 2 vertical loops, both hung from the same skyhook, one broadside north/south, and the other broadside east/west, and fed at the same point.

You get a more omni radiation pattern, but not full omni, there are still lobes. This is much like 2 crossed dipoles (for the same band) in an "X" configuration. Depending on height, you may not need the 2:1 balun. Check your impedance, a coax wound balun for a choke may be all that is necessary.

Ive never seen them connected in parallel but I have seen a relay at
the feed point that allowed you to select N/S or E/W. I think that you
could connect the way the OP mentioned with no big problem as far as
impedance matching goes.

Thanks, all I had to do a little tweaking on the matching coil to get a good match using my home brewed 5/8 with the bottom section but all is well.

AEA wasn't joking about wearing gloves and being careful of sharp edges, I got a nasty little cut when I dropped it and tried to catch it.

We have talked about them at length here. What was described is a
quadrifilar helix - without the helix.

As there are so many details of construction are missing, little more
can be said, and our original poster appears to have gotten bored with
the topic.

Hello Libra,

I expected some reply from the original poster to know whether we are thinking in the right direction or not.

When you put them 90 degr. to each other (for example E/W and one N/S), you will not get an omni-pattern. In that case you must make them both off-resonance to get 90 degr phase time shift in generated fields (or use a 90 degr. phase shifter and feed them separately).

I did not try this at HF. If I would make something, my first feeling is to use a relay or other form of switching. This enables me to select the loop with best signal and signal/noise ratio.

Best regards,

Wim

Hi Wim,

You can do it with a goniometer. This antenna was first described 103
years ago by Bellini and Tosi.

Richard
Please share the rest of the story. If we lay out multi length
radials for the middle of each band, say four of them, and feed the
vertical with the auto tuner would we be able to make it work on
eighty, and forty? When we use a half wave end fed zep in the form of
a J pole on two meters we don't need a counterpoise. If I extend this
mast to a half wave on forty will I still need a counterpoise?

Jim
I had no intention of running a four square with four auto tuners.
Perhaps I should have put that inquiry into a separate posting for the
sake of clarity. We built a four square for field day two years ago.
Because the masts that we had then were only thirty feet high a kind
of capacitance hat was built into the guy lines. We had very good
performance from that four square until a severe thunderstorm
destroyed it. I was wondering if having sixty four foot masts would
allow us to adjust the height to resonance on forty meters so that the
four masts themselves could serve as the elements of the four square.
Since a half wave at 7150 kHz is nearly sixty seven feet I would have
to add three feet worth of additional tubing in order to get a
resonant half wave antenna. I had thought that half wave verticals
did not require a counterpoise was I misinformed? If a counterpoise
is needed it wouldn't be too hard to throw out four radials for each
mast. I was just looking for a quick way to put up a four square and
these aluminum masts seemed like they might fill the bill.

Tom, is this a serious exercise here? This is just way too much trouble
for a 40 meter antenna.

Some antennas like the half wave verticals, don't require radials. But
I see a vacillating back and forth between high performance and well,
these verticals, which really aren't High performance.

As for several 64 foot masts, Why not go to one mast and put up a 40
meter beam beam? Add an Amp, and you will rule the air. Although I
wouldn't do that personally, because I would imagine that the idea of
emergency ops is getting set up and running ASAP.

It could be a matter of temperament I guess. You can get most of your
needed performance out of a simple dipole. But if you want to wring the
last drop of performance, I'd have to think the beam would take less

time to set up and perform better than a 4-square. You don't want to finish installing and tuning just at the time they send everyone home.

You'll need to have some loads on the vertical also.

That will be one interesting antenna.

Is there some reason that you are fixing on a vertical?

Hi Tom,

Thanx for something more specific that we can get our teeth into.

If you lay out radials that are tuned, such as you suggest, then you
wouldn't need an autotuner. There is, of course, the state of tune in
the radiator that needs to be accounted for, and I suppose the
autotuner would be put to work in that regard.

If so, then you are putting too much effort into the tune of the
radials. On the third hand, it doesn't hurt in the overall effort.

If you are going to have an autotuner (is this at the base of the
radiator, or back in the shack?); then there is a simpler and probably
more efficient use of the radial wire.

Over the years, the topic of how many and how long of radials with a
horizontal has had so many variables that the discussion ran to
examining the trivial instead of being useful. The useful advice is
to lay down as many radials as you can, but with a couple to three
dozen being a comfortable upper limit instead of the classic 120.
Their length should be equal to the radiator's height.

This doesn't make for a "tuned" vertical (except, perhaps, on some
frequency that probably is not in a Ham band if the height of the
antenna is ad-hoc); but it will be as efficient as is practicable. You
will still have to tune it. You will still suffer transmission line
loss related to the SWR exhibited at the feedpoint. It can be
unmanageable if its dimension approaches half-wave. Some of these
negatives can be managed by tuning the feedpoint with matching and
this is why I asked where the autotuner was located.

You anticipate the half-wave in your last question. The classical
answer there is no, you won't need a standard ground treatment. But
if you don't have some thing there, then tuning may become a chore
because the radiator, whatever its length, is always HALF of the

system. The radials typically are thought of as the other half. If you don't have any, your transmission line will take up that function in one way or another, and often to your annoyance.

As for the JPole discussion. Many who crow about their being simple tunes and there being no problems with matching, some are simply experiencing the transmission line being brought both into the tune and the radiation. The second part of that equation lengthens the overall radiator and sends the signal skyward. Yes, it tuned up fine, but you then have a deaf antenna - suitable for the local repeater, but so is an elevated rubber ducky.

Somehow, that didn't come out right.

The number and length of radials is, of course, confined to the
discussion of a vertical antenna.

The number of variables in this relates to frequency, match,
efficiency, loss (which at first blush the last two "seem" to be about
the same thing), and (incorrectly) launch angle.

Another point that occurred to me: The notion of a tuned radial, and
it laying on the ground is an exercise in futility. The proximity of
ground is going to seriously detune the radial which will mock your
effort. Tuned radials are more a property of elevated verticals. Some
commercial verticals which come with tuned radials, or where you will
be expected to supply them, have a tacit expectation of your also
mounting the antenna some appreciable distance above ground.

Previous probably lived in a desert without rain/snow. If twere mine,I would disassemble and set the traps so the holes are at the bottom when the antenna is installed.

Most probably the antenna was on a tilting tower and was assembled with the tower that way. Holes were down at that time! If you are going to use screws again, the correct method is to drill the outside tube, deburr it, assemble the way you want it, and then use an ice pick or similar to punch a starting hole in the inner tubing and then run the screw in. Much better holding power. If a pilot hole is drilled in both tubes, together, wind vibration will enlarge the hole and work the screw loose.

If you put the feedpoint in the middle of the antenna and run the coax up the middle of the bottom, and have a really good choke, it might work. (basically, an elevated half wave dipole) There was such an antenna scheme for a 4 square in one of the ARRL antenna compendiums (I think they were doing it for 160m, and had a matching network (mostly inductance) at the feedpoint to deal with the "electrically short" radiator.

Making it actually work is another story entirely. You've got to have a pretty good choke, or the feedline starts to be a big part of the system, and since it's laying on the ground, it's a pretty lossy part of the system. The bottom half of the antenna is closer to the ground than the top half, so there's those effects too.

SO, even if you sat at the bottom of the antenna with your antenna tuning meter and carefully adjusted the matching network at the feed to get 50 ohms, I don't know that when you set it all up, the phasing will be right.

It might be close enough.. but the odds of not getting as good a F/B as you want (e.g. null depth) are pretty good. The phasing isn't so critical for forward gain (you can be tens of degrees off and not lose much in forward gain, but that will completely kill your 10dB null)

But just feeding the end of a 1/2 wave wire sticking in the air is asking for difficulties. Your coax is nominally 50 ohm sort of impedance, and you'd be end feeding a dipole at a high Z point (a thousand ohms, maybe).

Two points:

1. The ARRL Mobile Manual had a bunch of homebrew antenna projects, some built from parts and some built from military surplus bits and pieces. Back then, a _lot_ of hams were running homebrew antennae.

2. There are a lot of military surplus mobile antennae available from Fair Radio Sales, and again that stuff was a lot more popular back in the fifties and sixties than purpose-built ham antennae.

Hello agn, everybody:

My apologies to you all. No, I have not gotten bored with this topic.
My job has rotating schedules as well as mandatory overtime.
Unfortunately, when one gets "stuck" for o/t, it's usually for an
entire extra 8-1/2 tour. When I finally get home, (A nice hike, btw!)
I either attend to my familial obligations or just crash. I did manage
to work a 5R8 station on the bottom of 80 so all was not lost - hihi.

I was thinking of making use of some unused space on my 50' fiberglass
mast by mounting a 2:1 balun and having two 10m vertically polarized
delta loops sharing the same feed points, specifically the
aforementioned balun. Yes, the goal is a single band, quiet and
physically unobtrusive single-band omni-directional. (Or at least
somewhat omni-directional without being a cloudburner.) Visualize, if
you will, two wire Christmas tree shaped wire loops, 90 degrees from
one another, fed at the center of their bottom legs up abt 30'.

Some might say, "why not just mount a vertical?" Well, I have the 2:1
balun and I figured that the loop would be much quieter.

Thanks so much for all your responses and have a safe and wonderful
weekend. Take care es...

I ran a single loop like you are talking about on 10M and had to use a
75 ohm 1/4 wl transformer to match the approximately 100 ohm impedance
of the loop.

I would think the two antennas mounted at right angles to each other
should be a pretty good match for 50 ohms.

Hi Bert,

This is the design of Bellini and Tosi of 105 years ago. They fed it
through a goniometer so they could steer the beam angle. At the time
they were unconcerned with load Z as you could tune the final and
drive to accomodate that.

>Some might say, "why not just mount a vertical?" Well, I have the 2:1
>balun and I figured that the loop would be much quieter.

I'm not sure how you have come up with, or plan to come up with a 2:1
BalUn - not very common, and construction details may ruin
expectations for performance.

As for "quieter," that is a very common myth = t'ain't so.

As for other details, you only roughly describe the length of wire
involved (in only one dimension) and you say nothing of frequency -
except by inference in the 80M band. Such details impact Z
considerably if you want someone to supply you with that
characteristic.

I want this to be a 10m semi-omnidirectional antenna. (Clover leaf
pattern I'd guess. Omni enough fo me.) My reference to 80m was just a
passing statement re. my schedule. Take care es...

Hi Bert,

Sounds like more than 1 wavelength of wire in the loop(s) then - no
matter, except this has a significant effect on drive Z. Look at
Jimmie's comment.

If you want to try something truly exotic, a steerable beam a la
Bellini and Tosi, then google their names with goniometer (an item you
can homebrew with some slight effort). The Adcock antenna is a
variation on this them (but without the goniometer).

http://g1inf.blogspot.com/
offers enough information to launch this idea. You will note the
EXACT antenna shape you described.

If I'm understanding this, what you are proposing would actually be
horizontally polarized, not vertical.
I imagine the triangle shape distorts things, but in general if you
feed a loop at either the top or the bottom, it will be horizontal.
You want to feed from one of the sides for it to be vertical.
Which calls for a square for most people..
Actually, what you want to build is very common. Most refer
to them as an "eggbeater". The usual method of feeding the
elements is 90 degrees out of phase if I remember right.
That gives the most omnidirectional pattern.

>
> Some might say, "why not just mount a vertical?" Well, I have the 2:1
> balun and I figured that the loop would be much quieter.

As Richard mentioned, this is fiction. All antennas receive noise.
How much you receive depends on the polarity of the antenna, the
noise source, and the efficiency of the system. It's quite possible
for
the horizontal antenna to receive the most noise if the noise is
radiated from a horizontal source. It's possible for an antenna to be
very "quiet" if it's very inefficient. Actually, if I notice an
antenna that is
too "quiet" I start to wonder what the heck is wrong with it.. :/
Noisy is good. Maybe not the noise itself, but that you receive it
well is good. You don't want it any other way, unless maybe you
are a proponent of the Unwintennas which tend to be air cooled
dummy loads.. :(

A good elevated vertical is actually a very good 10m antenna.
It's good for DX, but it's also good for space wave coverage to
locals.

Hello Bert,

When it is quieter and isn't a dummy load, it is more or less a
cloudburner. The reason for more noise is mostly caused by less
elevation of the main lobe due to the interference from the ground
reflection. This is what you want for line-of-sight and DX.

The vertical is a good option for sky wave and line-of-sight. When you make it electrically a half wave, requirements for ground are very limited. The only disadvantage is the matching section as the impedance at half wave resonance is rather high (up to 1 kOhm for thin conductors). When you run high power, you have to evaluate your construction for corona discharge.

Maybe you can use parts from CB antennas.

I'm considering building the bow-tie TV antenna at:

http://uhfhdtvantenna.blogspot.com/

It appears to cover the UHF range, but I also need reception on the lower 200MHz VHF range for the lower channels.

How can I combine the UHF bow-tie antenna with a folded dipole or other lower frequency element so the antenna covers the entire TV range from channel 2 to 62?

Hi Bill,

If you want to dance all the dances, you have to pay the piper.

Having one design that works should motivate you to scale a second one
to the lower bands. The piper's price is that the second one will be
that much larger than the first.

With a diplexer. That's a high pass filter for the UHF frequencies,
and a low pass filter for the VHF frequencies. You can place the two
antennas anywhere, combine them at the diplexer where convenient, and
run a single coax cable to the TV.

<http://www.antennasdirect.com/antenna_combiner.html>
I'm sure there are more (but I'm having problems finding any).

You can also use an ordinary TV splitter to do the same thing.
However, you'll incur about a -1dB loss for each port.

Appreciate all the replies received, direct and via the group.
I got my license in 1960 at age of 15. Everyone has a tendency to "collect" something..my interest in mobile antennas goes away back.
Operating HF Mobile is one of the greatest thrills I know of, including QRP!
The Magic of Radio still prevails !

Now that I'm retired, I can obtain some of these antennas and compare them with on the air evaluation..Not quite an Antenna shootout, but my own evaluation.

Doubt that I can sell them to Newer Hams when I'm ready to dispose of them, so will likely donate them to a local Radio Museum where the youth can see that many mobile antennas were not Screwdriver Antennas.

Don't use an 'ordinary TV splitter' (wideband) to combine two antennas.
The results can be very unpredictable. [The loss, by the way, will be
typically 3.5 to 4dB, but that's not the problem.] Definitely use a
proper diplexer.

The lower band is much narrower, so I figured a folded dipole would be easier to add, rather than another larger broadband bow-tie. And both the bow-tie and folded dipole impedances are around 300 ohms. But if I put the two in parallel the impedance goes to 150 ohms, which doesn't match the coax using one of those little transformers (300 to 75 ohm). So, I was just wondering how to keep the thing loaded for max power transfer? If I use high and low pass filters, does that keep the thing in balance?

Hi Bill,

There's every chance that it doesn't matter.

A folded dipole is not in and of itself widebanded in the sense of
your needs, and matching Z is not the end-all-be-all. More problems
come from a lack of directivity, but in this era of DTV even ghosts
can be digitally compensated for.

Consider the virtues of a fan dipole. If you want to force a Z match
through folding, make it a folded fan dipole.

Gotcha. If the TV splitter were used with a transmitter, where the
common port is driving two loads, the power will divide equally
between the two loads, resulting in a 3dB loss (minus about 0.5 to
1.0dB internal loss), as you describe. However, in receive, in the
other direction, the splitter isolates the two antennas from each
other by about 20dB. All the power is delivered to the common port
(minus about 0.5 to 1.0dB internal loss). Admittedly, the losses in a
proper diplexer are perhaps 1dB less than a splitter, but for a
receive only TV system, that's acceptable.

There are some dual-band or dual-frequency antenna designs where the two
feeders are connected in parallel at a specific distance from the
antenna, or where the active elements have a common feed point. However,
this only can be done if the antenna system is specifically designed to
operate like this. For general DIY, to avoid a good chance of being
disappointed, it is far safer to use a proper diplexer.

Not really a "Gotcha", many tv spitters are resistive with 3 or even 6dB
of real loss.

The VHF band covers a 4:1 frequency range, split into about 1.6:1 range for the low VHF (channels 2 - 6) and 1.24:1 for the high VHF (channels 7 - 13). No simple antenna will have anything like a constant impedance over this range, so you're going to have a considerable mismatch on some channels no matter what you do. The good news, though, is that the mismatch loss won't exceed 3 dB until the SWR goes over 5:1. And unless you're in a really fringe area, you can probably tolerate quite a high loss. (At my QTH, I've had to add an attenuator pad to prevent signals from overloading the TV.)

A trick often used for VHF TV antennas is to size the antenna for the low VHF channels, but bend the element ends 30 degrees to form a broad vee shape. The antenna functions as an approximately 3/2 wave antenna with moderately good impedance at the high VHF channels, and the bending aligns the lobes to maintain a bidirectional rather than multi-lobed pattern at the higher channels. The bending has a minimal effect on the impedance and pattern on the lower channels. This trick works well for a 40/15 meter antenna, by the way.

Hi All,

As a sidebar, the design described is sometimes a precision splitter/combiner/attenuator. As odd as it may seem, such designs are very stable over considerable spans of frequency when premium components and good layout are taken into consideration. I would peg their loss higher with at least 10dB, however. For TV applications, that 3dB loss would be a minimum.

Only a 'transformer' splitter can have a through-loss of 3dB.

Actually, it is theoretically 'lossless'. The 3dB loss isn't a loss at
all. It's 3dB because the power is split into two equal paths. In
practice, there is some real through loss - typically 0.5dB at 50MHz,
rising to over 1.5dB at 900MHz, so the measured through-loss will be 3.5
- 4.5dB.

A two-way resistive splitter has usually consists of a star of nominally
25 ohm resistors (usually 24 or 27 ohms). Like the transformer splitter,
all three ports are correctly matched (when the other two are also
correctly terminated. The through-loss is a theoretical 6dB (as opposed
to the 3dB of the transformer splitter). 3dB is the power split, and 3dB

is lost in the resistors.

The practical loss is usually also 6db and, if you use the correct type of resistors, this is maintained to 900MHz. In fact, because of stray capacitive coupling across the resistors, the loss may actually decrease. Of course, the isolation between outputs is only 6dB (the same as the through-loss). The resistive splitter must be considered 'cheap and cheerful' compared with the transformer version. However, it does have its uses.

There are some 'economy' versions of the resistive splitter, which are simply 'Y' splitters, where there is a nominal 37.5 ohm resistor (typically 33 or 39 ohms) between the input and each output. The through-loss is lower, at around 4.5dB, but only the input is matched. There is no isolation between the outputs.

Just about all the VHF/UHF TV Yagi antennas are like that. Some
examples:
<http://www.hdtvprimer.com/ANTENNAS/comparing.html>
<http://www.hdtvprimer.com/SIMS/>

However, I'm talking about how the splitter/combiner operates.
Ignoring internal losses, going into the common port, the power
divides equally between the two output ports for a -3dB theoretical
loss per port. However, going into either port, does NOT divide the
power between the other antenna port and the common port. It all goes

to the common port, with no loss (other than internal losses). In receive, this loss is not your stated -3.5 to -4dB, but more like -1dB. The labeling on the typical splitter shows the -3.5dB loss per port, which is correct for a signal going into the common port (acting as a splitter). See specifications at:
<http://www.channelmasterstore.com/ProductDetails.asp?ProductCode=CM-3212&Show=TechSpecs>
It's NOT correct for the other direction (acting as a combiner), which is the manner I'm suggesting the OP combine two antennas.

However, there's an additional problem. Because the two antennas can both pickup some signal from a given station, there's no way to predict what will happen when the signals both meet at the splitter/combiner. Most likely the pattern and gain will be affected depending on the relative signal strengths. If this is a problem, then a diplexer should be used.

1218. Paralleling Transmission Lines

Newsgroup: rec.radio.amateur.antenna
Date: 2010-04-20 19:37:02 UTC
From: Cecil Moore <w5dxp@hotmail.com>
Message-ID: <d6ea0bf4-7bb4-4089-9c88-9d2d9e8d1387@s7g2000vbk.googlegroups.com>
Source record: 10216

What happens when two paralleled transmission lines are of different lengths? How does one analyze such a problem? For instance, what impedance is seen at the source when a 30 foot run of 450 ohm ladder-line is paralleled with a 20 foot run of the same line when the common load is 100+j200 ohms? Will EZNEC handle such a problem? What if the two different length paralleled transmission lines are not the same VF and/or not the same Z0? Does superposition work for such a problem?

This type of RF splitter/ combiner is completely bi-directional. The losses are exactly the same either way. The one exception is when combining, you only get no loss provided you feed identical signals (frequency, amplitude and phase) into the two inputs. As there will no voltage across the internal load resistor (which, in a 75 ohm device, is a nominal 150 ohms, effectively connected across the inputs), there will be no current through it, and hence no power loss.

However, for two unrelated RF inputs (say, two different TV signals), you will absolutely definitely get a 3dB loss (plus the additional losses). There is theoretically infinite (typically 20 to 35) isolation between the inputs. Feed a signal into I/P1, and no signal appears at I/P2 (if the output is correctly terminated). There must therefore be a voltage across the load resistor, and current through it. The power lost in this resistor is half the input power (-3dB's worth). The other half goes to the output (hence the 3dB loss).

Indeed. These are the 'unpredictable results' to which I was referring (but decided not to get bogged down in!).

Well, my first impulse is to actually hang the two lines and measure
the resultant impedance at the source end...
I am assuming the lines are spread apart so that they are not closely
coupled...
One approach to get you in the ballpark would be to model the 30
footer alone to get a source impedance, then model the 20 footer
likewise alone, then model the resultant of those two complex
impedance in parallel...
An interesting question...

Argh. You're right, I'm wrong. The loss is symmetrical. My
apologies for offering a bad suggestion and worse explanation.

(Gone somewhere to sulk...)

I'm puzzled, Cecil. I wouldn't think a simple linear system like this would be difficult for you to analyze. (Or perhaps you do know how, and are only testing to see if others do also.) With respect to R.R.A.A., under what circumstances would such a configuration ever arise in practice? And...why would you think to use an antenna modeling program to analyze a linear circuits problem? Why not pick a tool appropriate to the task?

Cheers,
Tom

Old age, Jeff. Old age!
It happens to us all - even me.
For example, in my description of the 'economy version of the resistive
splitter, I said "There is no isolation between the outputs". This is,
of course, not true. There will be a few dB isolation (but I can't be
bothered to do the figuring!).

Worse. I made the same exact mistake years ago in the NEC-LIST (July
2001). I never make the same mistake twice. Four or five times is
more my style. Thanks for the correction.

Not old age (62) but possibly a good excuse for a vacation.

Nope, not a trick question. The thought occurred to me after a liter
of Merlot. It is akin to the analysis of a fan dipole except shorted
at both ends. If 30 feet is not the optimum length for the matching
section of a G5RV used on 30m, what if we paralleled the non-optimum
length section with the optimum length section? What happens then?

It appears that what happens is that we lower the resistance while
maintaining the reactance at a high level - not a good thing. File it
under " unfortunate wet dreams".

Here is an opportunity for you to do some leg work Cecil.

I have modelled in RFSIM99 a load of 100 ohms in series with 9.1ΩH at 3.5MHz with 30' of lossless 400 ohm line, vf=0.9, and 20' of lossless 450 ohm line, vf=0.8 as you describe. The input impedance is 767+j296.

Do you get the same result with a valid model in EZNEC?

Owen

Bill,
Check the actual transmission frequencies that are used in your araa.
www.tvfool.com or antennaweb will list them for you. Durring
the switchover to DTV, many of the lower VHF channels were vacated
and the broadcasters relocated to the UHF band. They may still
identify themselves as their old channel number, tho. Anyway,
you may find that your design criteria are much simplified if
you discover that there are no broadcasts in the low VHF band.
And FWIW, I have had good luck with just two commercial bowties
on a stick. (see,
http://mysite.ncnetwork.net/resr92x4/Content/DTV_antenna.html)

It does well even at the high VHF band. Althought we were having
trouble with one channel in the low VHF untill it moved after the
DTV changeover.

Oh, and IIRC, the UHF only goes to channel 52 now.(?)

Remarkably, Owen, I get exactly the same result using LTSpice.

Spice and RFSim99 are the two that came to mind when I wrote about more appropriate modeling tools yesterday... It might be fun to find the general solution to the set of linear equations relating the forward and reverse voltage and current at each end of each line and in the load, for a given excitation, to end up with a relatively simple (?) formula for translating the load impedance to the impedance seen at the input end of the lines, and maybe that already exists in a text or reference book somewhere, but there are a few too many equations in the set to get me interested in doing it by hand.

It's also interesting that in both this example and in another different one I tried yesterday, I found that, at some frequency (16.993MHz for Owen's example), the impedance at the input goes to infinity. That is to say, there is no current in the load: the load is at a point along the loop of two lines that is at a zero-voltage point of the standing wave. It shouldn't be a surprise that this happens, but you might not think about it when just blindly connecting two lines of different lengths "in parallel," and end up getting bitten by it.

Cheers,
Tom

Well Tom, perhaps it is that "great minds think alike".

Cecil's question on eHam and then here specifically asked if EZNEC can solved it, but mused that it needed information about the reflection at (presumably a source side) ATU. Of course, the source side circuitry is irrelevant to a steady state solution of the input impedance that we both calculated.

I am not sure that it has any specific application, but the rat race hybrid is an expanded problem of the same type.

As far as I can see, NEC must have the ability to solve networks of elements that can be represented as NT cards, just that the GW elements that you use to hook it all together are subject to mutual coupling (which is appropriate if it were a real feedline / antenna scenario).

It took me less time to build and check the RFSIM99 model than it took Cecil to write his post. It would take only a little longer in NEC.

Source record: 10240

Dear Bill (no call sign): Others may have pointed out that most TV stations in U.S.A. are on UHF from channels 14 to 51, with a minority on VHF. A student project was to design an antenna to cover 14-51 with useful results.

A simple two-dipoles-in-front-of-reflector antenna is being sold where the dipoles include a fat, short part and a thin, long part so as to cover UHF and the 7-12 VHF bands.

The link to tvfool.comor doesn't work, but I found a listing for the
Los Angeles area at http://yourfreedtv.com/Hollywood/

Most of the stations are good using an old antenna, but channel 24
drops out and I don't get 23 at all. Looks like the range is RF
channels 23 to 60, whatever frequencies they are. I can't get channels
23 or 24 which correspond to RF channels 23-26, and look like the
lower end of the band. It's interesting that channel 2 which used to
be the low end of the VHF band is now RF channel 60 near the high end
of the UHF band.

It appears that you didn't understand the purpose of my original
posting. Days before, I had already run the EZNEC impedance results
but was questioning the validity of those impedance values. Tuner
settings are certainly not irrelevant when calculating system
efficiency which was my main goal. The musing was whether the results
of two different tuner settings could be superposed.

> It took me less time to build and check the RFSIM99 model than it took

Days before my original posting using EZNEC, I had already paralleled
a 20 foot section of ladder-line with the standard 30 foot section on
a G5RV but I had no quick and easy way of independently verifying
EZNEC's impedance results. It was only after a lot of effort that I
still had questions. Thanks for the information - if not for jumping
to false conclusions based on ignorance.

Its a dead loss. The WIA's guidelines on callsigns are not very clear.

If the callsign is available you should have the right to apply for it, just like when the ACMA administered the callsigns. These callsigns are clearly not allocated on the first come first serve basis, but on some other arbitrary set of rules that nobody knows.

If you look at the history of the 2 letter callsigns allocated you see a clear preference towards clubs and its officials, one off individuals are low down in the preference ranks. The callsigns are not being administered in way thats fair to the broader amateur community.

I now several people who have applied in consistent manner multiple time. One person actually lodged several applications within 1 hour of the callsigns been listed. He lives in the same post office zone and the applications were mailed with the same day. You can understand his skepticism.

It would have been far better if the callsigns administration was in the hands of some independent body not related to ham radio. A simpler fairer impartial system would have to use a automated secure online immediate transaction system., just like they sell tickets. In the past it too 30 mins for the ACMA to allocate a call why the WIA takes weeks is beyond me.

What i have experience so far, is that I have little faith in WIA allocating these 2 letter calls. I wonder if the process is open to legal independent scrutiny? Does the ACMA audit the process I wonder?

Dear Walt,

Ever since reading your 1973 QST articles, being a second-year student at the Polytechnics/Technical University of Copenhagen, I have referred to your ground-breaking work for removing the myths and misunderstandings of the (un)importance of the swr over and over again. Somewhere I still have the ageing photocopies of all the articles. But having the opportunity to get it all and more in one piece in Reflections III is really greast. I have ordered my copy right away.

Later on, both in my professional life after receiving my MSc(EE) as a radio engineer and during my 19 years as Technical Editor of 'OZ' (the Danisk QST) I have had to weed out misconceptions about swr and transmission lines. My early understanding from your work was a great help. Thanks!

All the best,

vy 73

I've seen people talking about it in the other forums, and I looked at the three sample excerpts at w2du.com. That's all I know about it. It sounds interesting, but I need to at least see a table of contents (index would be nice, too) before I think about ordering it. Is that possible?

TIA.

1255. SWR on Diamond X-200A

Newsgroup: rec.radio.amateur.antenna
Date: 2010-04-25 19:16:52 UTC
From: Chuck Forsberg WA7KGX N2469R <caf@omen.com>
Message-ID: <8-KdncYwcbi5CEnWnZ2dnUVZ_h6dnZ2d@giganews.com>
Source record: 10153

I installed a Diamond X-200A antenna just above a Thunderbird TH5MK2 tribander. Due to a short mast, the Diamond is virtually sitting on top of the Thunderbird.

The lead-in consists of some 20 feet of 9914f and 50 feet of 9913, connected with UHF connectors.

The measured SWR minimum is at 147.7 MHz and 1.2:1 at the far end of the coax. The MFJ 259B reads 1.9:1 at 144 mHz. Presumably the SWR is a bit higher at the antenna connector.

If I use a longer mast to raise the Diamond above the tribander, can I expect the resonant point to move to the specified 146 MHz and the SWR at 144 to go down? How much separation is needed?

Ok, from TLLC (http://www.vk1od.net/calc/tl/tllc.php) you have about
1.1dB of line loss if everything is in good condition.

I assume all readings were made with the same instrument.

Your load end VSWR at minimum is close to 1.3, which is typical of those
type of things. The frequency of the minimum does seem a bit high.

I am a bit surprised that it is that far off, and wouldn't expect a lot
of change in raising it... but you only know if you try it.

Have you used / measured it in other scenarios?

Have you measured the VSWR characteristic using a conventional
reflectometer style instrument at modest power? Does it agree with the
'259B?

The 9913 is infamous for getting water inside of it. This is usally
indicated bu an unusually low and broad banded VSWR reading. There
should be some good info on the internet about "stacking antennas" I
think some of those who loiter on this NG have written some papers on
it, I seem to remember Owen but I may be wrong.

Jimmie, I did write a paper on optimum stacking distance for DL6WU long Yagis, but that is quite a different situation to that in which Chuck finds himself.

Your comment about the coax is valid, and all elements should be checked.

I might also add Chuck, that some folk have described minimum VSWR being shifted, and attributed it to faulty ceramic caps in the network at the base of the antenna.

But first, does it behave properly when mounted in the clear. If so, it probably isn't faulty, but its environment the likely cause.

I checked the 9913 and discarded some of it where there had been a hint
of water ingress. In this instance, the SWR is a bit higher than Diamond
shows in its chart. The SWR minimum at first glance is no broader than
spec - it's just at the high end of the band instead of the middle.

Later this week I should know if separating it further from the Thunderbird
will change things.

Radio Shack part number 15-2586, a combiner/splitter for UHF and VHF signals. I have one and I ran some tests on it and it works well -- low insertion loss (< 1 dB) for the UHF signals at the UHF port and about 15 dB rejection for the undesired VHF signals at the UHF port. I didn't take any readings at the VHF port but it worked well in-circuit, so it's worth a try.

Good luck with your antennas.

That page is a ramble.

Example: Can someone tell me which line number offers the meaning for
Diversity? I am not interested in interpretations of Tom, nor
abstractions culled together from disjoint statements. I want to know
where (literally, not figuratively) Tom defines what Diversity is.

I don't think it was intended to be much more than a discussion of a
specific type of single antenna diversity reception plus something
about stereo-like diversity.

>Example: Can someone tell me which line number offers the meaning for
>Diversity?

A link to the Wikipedia page would probably have been sufficient:
<http://en.wikipedia.org/wiki/Diversity_scheme>
The problem is that NONE of the diversity schemes mentioned in the
Wikipedia article apply to the single antenna example under
discussion. In my never humble opinion, there's no way to provide any
form of diversity reception improvement with a single antenna, unless
one also has two feeds, going to two different receivers, and ending
in either a decision switch, or some form of intelligent combiner.

>I am not interested in interpretations of Tom, nor
>abstractions culled together from disjoint statements.

How about my definition? No matter which scheme is used, a diversity
reception scheme must demonstrate an improvement in availability, BER,
or SNR over a single antenna, or it's not really diversity.

>I want to know
>where (literally, not figuratively) Tom defines what Diversity is.

He doesn't.

I'm rather confused as to his "stereo diversity" which I guess uses
the listeners ears and brain as the decision switch or decoder. I

think he might be referring to a direct conversion receiver where one channel is quadrature leading and the other is quadrature lagging, resulting in a stereo-like effect.

So, this is an example of a "straw man" argument (not yours, Tom's): a
solution to a problem that is undefined. There are, thus, many
solutions that none can refute and why Tom's is the sine qua non is
built on a foundation of sand.

>In my never humble opinion, there's no way to provide any
>form of diversity reception improvement with a single antenna, unless
>one also has two feeds, going to two different receivers, and ending

Well, to Tom's credit, there is ample discussion of that - but that
discussion does not answer the question, which means there is no way
to test for validity.

>>I am not interested in interpretations of Tom, nor
>>abstractions culled together from disjoint statements.
>
>How about my definition?

Sorry, Jeff, but unless you are the author of the Wikipedia reference,
I cannot answer your question.

>No matter which scheme is used, a diversity
>reception scheme must demonstrate an improvement in availability, BER,
>or SNR over a single antenna, or it's not really diversity.

I presume the statement above is your definition. Reducing S+N/N
satisfies what you call diversity and provides an example of a
self-referential definition in that you appeal to with "SNR." Self
referential definitions are logical nulls. In other words, does
increasing capture area qualify as diversity for a single antenna? If
so, diversity means less noise or a better signal in comparison. What
is diverse about ordinary directivity? What is the profit in having
two words describe the same thing?

Even with an informal presumption of the meaning of diversity, we can both agree that diversity is not also directivity.

Or perhaps it is that, and with one characteristic more. This returns us to the question with some refinement: what is diversity in the face of directivity? I have a hunch directivity is a distraction, but that returns us to the original question.

>>I want to know
>>where (literally, not figuratively) Tom defines what Diversity is.
>
>He doesn't.

I didn't think so and I was asking because I didn't consider it worth the effort to search for something so obscured by the baggage of peripheral discussion.

>I'm rather confused as to his "stereo diversity" which I guess uses
>the listeners ears and brain as the decision switch or decoder. I
>think he might be referring to a direct conversion receiver where one
>channel is quadrature leading and the other is quadrature lagging,
>resulting in a stereo-like effect.

I will admit this was my interpretation too. Strange how you have to sift the diamonds out of the horse-shit. I had worked in this field and built quadrature detectors 40 years ago to the same ends as you describe. Analog TV color detection had been doing it for at least 20 years before that. I suppose there is a metaphor of diversity there, but it came with the subject of quadrature detection as a solution, not as a recent invention.

The quad detector is a direct conversion receiver as you say.

For other readers:
The signal is split through two channels each mixed with the same base-band source, with one feed of the source shifted 90 degrees for one channel. I suppose here we could drop the input splitter and simply feed in two antenna drives. The separate mixer outputs feed separate headphone elements (the classic application way back then) and the brain perceives the signal as existing in a literal 2D (binaural) space. The consequence of this perception is a heightened ability to discriminate one signal from the rest within the bandpass of reception. The bandpass is perceived as a physical left-to-right space and because the classic application was through headphones, this space was also between the ears. For the modern reader, this was like having a spectrum analyzer in your head.

This is the classic situation of being able to listen to one conversation in a crowded room full of speakers (the cocktail party problem) without becoming overwhelmed by overlapping dialog. A simple test is when you tune to the signal of interest, any off-frequency signals are perceived as inhabiting this 2D space at a literal off-center. As no two transmissions occupy the exact same frequency (Tom explicitly mentions errors as small as a quarter Hertz), then

they lose being at the center of attention. The brain supplies a huge computational engine that computers have yet to match.

The topic of Quad detection is cool in its own right, but I don't see how tarting it up with the discussion of Diversity (especially when the term is one of dim provenance) really adds anything. Quad detection read more like window dressing than the clincher to the topic at hand.

Hi Bill,

Well, diversity antenna work is quite useful to the average reader - I suppose (they haven't actually clamored for the discussion or embroiled themselves in the topic, but you did couch this in terms of "readers").

Unfortunately, if we divorced the two authors who fail to offer what Diversity means, apart from what is already accepted in convention, then we remove the entertainment value and "readership" would likely decline.

A paradox.

Sure, at least in a practical sense. I make use of diversity receivers in wireless microphone work.

While these are used at UHF frequencies rather than HF, our problems are more multipath, maybe picket fencing a bit.

So while I know better than to get into the definitions of diversity antennas, given my meager abilities, my guess is that if one antenna worked better than two - or merely worked at all, we'd be using just one.

Tom's pseudo stereo looks suspiciously like a wetware version of my wireless systems,only that they vote, whereas his signal levels are too low for that, so he does it in his head.

That is for certain.

Trying to wrap my mind around this...

I wouldn't know how splitting the signal to two receivers would work.
The issue arises at the antenna doesn't it?

Indeed, if a single wire antenna would work for diversity reception,
wouldn't it then follow that you would not have to use diversity
reception? The signal would already be there for you.

Seems like a simple test could answer this one.

I think the first place to start is to what the actual antenna pattern
represents in terms of polarity.
For instance, we have two vectors outside the earths boundary thus you
must have two vectors inside the arbitrary boundary. Obviously the
gravity vector will be at right angles to the earths surface. The
other vector representing the rotation of the earth will naturally be
an circular pattern which is the "saucer" pattern portion of the
overall pattern, which is what hams mainly use. Thus we have to make
the first determination as being what each portion of the pattern
represents in terms of polarity, the centre being straight plume field
and the bottom circular field which is a rotational vector. Since they
are in vector form we can see them as a stream of particles where the
two vectors will be additive. It is only then that the problem of
different or the same phase factors can be ascertained. Definitions
applied can be approach later. Personally, I view the gravity vector
as linear with the other providing a wobberly helical vector i.e
circular. but varying angles to the earths surface. Other thinkers
will surely disagree, if only to fight over near field over far field!

I have no doubt that gravity effects radio waves in the same manner
that it has been proven to effect light. The effects are going to be
such that unless your signal is passing by a black hole of no
practical concern.

Have a great day Art.

Ah! The nut of the problem.

To my knowledge, diversity forces you to find the signal elsewhere,
not in the same spot because it isn't there anymore, or at least not
in the same polarization. This last diversity (polarization) is but
one of many. It may be solved at the antenna that features multiple
polarization capability - here Tom's ramble throws EZNEC against the
wall to see what sticks, and he introduces new issues that distract.

There is space diversity, time diversity, phase diversity, frequency
diversity (and there are more if we consider more modulations) and all
we get is the all encompassing "diversity" being hung out to dry.

The distractions that I see discussed are problems of combining
signal, not in finding signal. Interesting problem there, but hardly
something noted to being an issue with an antenna. Someone will
correct my misapprehension in this thread if there is one.

if the pseudo stereo is derived from 2 different antennas then you
have diversity reception where the separate antennas provide different
signals that may fade at different times due to polarization changes
or incident angle changes... that is what tom was driving at as a
useful diversity system, albeit at the expense of more complex
receiver hardware.

when you take a single rf signal and split it through different receive processors to shift the phase, or do different sidebands, or just run through different high/low pass audio filters, you don't really have diversity, you have some kind of a processing system that makes it easier for your brain or some other decoder to sort out the signal from the noise. I played with some simple ones years ago and they can provide interesting effects that can make sorting out signals in pileups easier, or maybe pulling signals out of the noise a bit easier, but none of them will really prevent the multipath, arrival angle, or polarization fading. that is where tom was trying to point out that any way you combine the rf from two antennas into one you lose the advantages of the diversity of the antennas.

Totally wrong!
The vector inside the boundary opposes gravity!
The particle has a straight line trajectory and does not fall back to earth during that trajectory.The rotary vector supplies spin to the other vector force
just as the dimples in an golf ball or the rifling of a firearm barrel. These same vectors are represented
by time varying electrical current (straight line) as well as displacement current which generates a vortex by its circular motion. When the current flow is completely outside the surface of the radiator skin depth disappears as does resistance. So the radiator has a skin of tightly bonded particles upon which the straight line trajectory is imposed. Remember, earth gravity has zero effect on propagation inside a arbitrary boundary otherwise straight line projection could not exist.

I saw that bold statement as well, and then it was treated to a fog of
support.

At some point, the RF from two antennas must combine by the time it
hits our ears. That, or diversity reception means two people
listening to two sources and then matching notes - which means the RF
from the two antennas combine on the final page draft.

So, let me put this forward.
Two antennas
feeding two separate RF chain amplifiers
both chains mixed from a single LO
two separate mixers into IF chain amplifiers
--- somewhere they have to combine ----
two IFs into two detectors
two detectors into two separate audio chain amps
each audio chain driving a speaker element.

I have (gasp!) interpolated, interpreted, simply guessed, guessed
wrong, guessed right, about this single LO. Maybe it was in the
detector at the end of the IF chain. Whatever.

So, with this duality extending from antenna(s) to speaker(s), is the
prohibition against combining the RF from two antennas merely a
syllogism?

OK, backing up that chain to the concept of two separate RF chain
amplifiers. Lets just call it one RF chain amplifier or no RF
amplifiers and straight to a mixer. Is the prohibition at the
combining of RF from two antennas located at the mixer input? No
parallel connection?

This is getting ugly because it is not about diversity, and it is not
about antennas.

Welcome back, Art!

And I'm quite serious.

Obviously you are no longer taking your medications or maybe they just
let you out.

Please keep it up. I, for one, have missed your lack of connection to
reality. It is very amusing.

It's the amusing part. Totally useless technically, but often comprises
nearly 100% of the traffic on this group for days or weeks.

Tom
From my viewpoint which may well be unconventional,
may I point out that both elements as well as the array as a whole is
resonant and in equilibrium.
Thus in reality, you have two separate antennas that are additive and
go to the same receiver.
The receiver uses the addition of the two current flows or two
separate flows thus picking up both linear and non linear signals. So
I would suggest that the antenna is therefore sensitive to both .
phases(ie in phase and out of phase fields).
Ww8ji is of the opinion that the program is in error by virtue of the
statement it makes since it is unable to print the truth but doesn't
provide evidence of same.I believe he is looking at an array that is
not in equilibrium to arrive at his viewpoint.
Both elements pick up the same message with one having a delay in
time due to phase change regardles of what created it, deflection or
other wise. This is no different to viewing both elements as
mechanically vibrating and because the array as a whole is in
equilibrium both will vibrate in unison
Regards
Art

Perception is not the same as reality. A mixer in a radio is different
than what is required when seeking diversity. The first is the mixing
of two different frequencies where diversity requires the mixing of
two frequencies of the same except one has a delay. The output of the

latter is three traces where the two separate bone vibration of the ears can separate the two and where your middle ear can provide the summation. Your brain supplies the jumper of your choice. Without discovery you can abide with perception and not with change. With discoveries you must accept change. If all is known then one doesn't have to accept change and can exist without a brain by being a follower and not a leader.

The wife and I journied down to the drain portion of Illinois to visit
some of the older towns. One town alongside a river had a good side to
it but down town alongside the river seemed somewhat run down.
A walk down what originally was main street
was a collection of buildings some occupied and some not. Looked thru
the window of one and there were various pictures of the past, men
with bowler hats and women with long black dresses depicting the hard
times of the past which forewarned of its future.
On the wall at the side of the montage was a thermometer like diagram
showing the various water levels the river rose with one of which was
caused by the earthquake at Madrid Illinois and where the uppermost
point looked like the middle of the second floor. The next shop window
was empty as was the inside except for an easle holding up a picture
of George W Bush with the caption
Biggest disaster ever!
A wonderful example of English humour.

English humor is usually a little dryer than that.

Yeah, I think I agree with Tom's practical experience/experiment. I
certainly do not think that one antenna is going to do this diversity,
because if it would, it means that there is no need for any of the
diversity systems we know about today, with double antennas, voting

and/or dual receivers.

Richard's concerns are for the definition, which I think in Art's case, is probably important.

side foray here. Did you try binaural receivers? I've heard of them, never had a chance to listen to one.

I agree. One of the important factors as far as I know is that the antennas have to be in two different spots, and although I haven't measured, (I will now that I'm really interested) I'll bet that the best performance comes at a distance that is well related to the wavelength. Which is to say the picket fencing I hear on a mobile two meter signal might allow me to determine his velocity by knowing the frequency of the picket, the frequency of the transmission, with a likely but small error via Doppler shift.

But aside from that little foray, I have no doubt that the effects that call for diversity antennas/receivers also call for some physical separation of separate antennas.

Feeding it would be fairly easy.. But.. Just because it's a half
wave will not mean that there will be low ground losses if
ground mounted.
You would see less ground loss than a ground mount quarter
wave, but it could still be an issue. Note that most broadcasters
who run half waves, also use a set of half wave radials.
I'd probably rather use 32 ft masts supporting self supporting
32 ft radiators, and use a few sloping radials as radials, and
also to double as guy wires.
That will work fairly well with as few as three radials. More
to be optimum, but this is field day.. :/

And would strongly resemble the radiators at WWV...

If you do this, you'd put the AH4 at the join point too. For FD, you might want to have the bottom 8-10 feet of the guy/radial be an insulator, so that nobody touches the HV part of the antenna.

For diversity, something which you can take advantage of has to be different between signals from two antennas. They can be at the same physical location but, for example, have different polarization (polarization diversity). Or they can be physically separate (space diversity). However, a key necessity is that the signals from the two can't be phase coherent if you're combining them. That means you have to separately detect the two signals with receivers that aren't phase coherent -- you can't use a single LO for both -- then combine the signals after detection. If you do try to connect the antennas together or convert/detect them with the same LO, you'll simply have a single phased array antenna system.

If you're not combining them, but listening to one or the other but not both at the same time based on some sort of voting system, you can detect/convert them any way you want, including using the same LO.

Actually, the antennas can be co-located, they just have to have
different patterns. There are some researchers in France who did a lot
of work using an active whip next to an active loop.

A pair of crossed dipoles would probably also work, which would have the
advantage that you could use one of them to transmit with.

When I was an ET in the Air Force I had a TDY assignment attached to a
project with Hughes. They were attempting to to implement in software
what Tom was doing in wetware. The purpose was to send high speed(at
the time) radar data over HF SSB . The project was a success but the
final implementation was very different from "stereo diversity"
basically because they could not program a computer to do what the
brain can do very easily.

these days, though, it's pretty straightforward.. The whiz-bang MIMO
stuff you see in 802.11n, for instance is one flavor of diversity. Two
antennas at each end gives you 4 possible paths (A:1, A:2, B:1, B:2)
each of which will have different fading and interference properties.

It would be above ground level with a 32 ft mast. So that would
be no problem. I've used that antenna here at the house, except
I had the 32 ft radiator on a 36 ft mast. I used four radials and
sloped them down and tied off to trees, fences, whatever..
I would not use the AH4 tuner. No need.. The antenna would
be resonant. It would work pretty well on longer paths at night.
The same antenna can also be used for 17m if you add a
matching coil to use it as a 5/8 wave. I had a 24 volt relay
rigged up at the feed point of mine, and could switch from the
shack.

Okay, but I'd have to modify (my statement) that as there would have to be some difference in the antennas, even if co located. Some sort of difference that would make one antenna receive some particular signal better than another one. The crossed dipoles are an good example.

As Roy pointed out, it depends on the parameter in question.

I'm preparing an article for a local radio club magazine about the nature of radio and electromagnetic radiation in general. While this is a non mathematical and general descriptive treatment of the subject it is a challenge to make it clear and consistent.
I know this group has some expertise on this subject and would appreciate any constructive comment and suggestions regarding the attached article.

http://members.optushome.com.au/vk6ysf/vk6ysf/radio.htm

Thank you for your time.

The two-dimensional Fig. 2-2 graph is confusing in that it could be
inferred that the E and H fields are 90 degrees out of phase in time
and are never zero at the same time. The E and H fields are in phase
in time as demonstrated by Fig. 2-4.

Hmmm. I'm no expert, but I thought they were 90 degrees out of phase.
It's the rapidly changing H field that creates the E field and vica
versa. If you look closely, Fig 2-4 also shows them 90 degrees out of
phase.

To the OP, heat is not electromagnetic radiation. Light and x-rays
are. You can heat something by pointing em radiation at it and
something that is hot gives off infra-red em radiation, but heat
itself is not em radiation.

Pat

It is accepted that radiation is "an acceleration that generates or
transfers a charge ". This is an empty statement if one cannot explain
the mechanics of the operation.Certainly you have to determine what
you have in hand to provide this action, and at the present time there
is no agreement whether it is a wave flow of a constituent, what ever
that may be, or a particle.
Therefore one has to determine exactly what we are going to accelerate
and how we are going to avoid the effects of gravity since radiation
does not follow the action of a descending lob.
This as yet has not been determined, so we cannot begin to
understand! For me I see a wave as being an adjective and a particle
as a noun.
But a word of warning,physicists do not follow the same rules of the
general public, so if you have a day or two to spare get a physicist
to explain exactly what a 'wave' is and how does it fit with the
required straight line accelerating trajectory that opposes gravity!
You just cannot explain "radio" until you determine what you are
accelerating and how.

Sorry about that

Hi Peter,

Yes, your treatment does tend to veer towards the exotic topics.

Stick to the basics. You have a wonderful resource that you point to in the Navy training manuals. As a former instructor for the Navy's Electronic Technician A and C schools, I can attest this material manages the balance between technical and theoretical.

You may notice that the first manual introduces the concept of photons, but no where goes into "duality." And for good reason, it doesn't matter one whit. When you raise this concept, the weaker participants of your audience would then think about solar particles in competition with solar radiation (light, largely). They would probably miss the vast difference in propagation speed.

Solar radiation, of course, travels at the speed of light. This is why it is called radiation. Solar particles (the erroneous dual to the photon) travels at less than 1% of the speed of light. If any of your audience were to simply consider their final's tubes, within that glass enclosure, electrons travel at 90% of the speed of light. Dribble a little air into that vacuum tube, and the speed of any electron would plummet to inches per hour.

So, what value is there in opening that can of worms?

Obviously a problem here! Quantum mechanics states radio rotates
around particles and classical physics revolves about waves. If
radiation is an acceleration of charge then it is pivotable that one
decides what is being accelerated in the first place!
If Einstein is correct that the speed of light is not to be exceeded
then one has to decide whether a wave is lighter than the smallest
particle possible.
Waves do have length a physicist would say where as a particle can be

a point! How we get straight line trajectory while gravity is present is easily solved. Pysicists have now removed gravity from the Standard Model to get over that problem.The Navy on the other hand ignores the duallity question.

The time phase angle between E and H is determined by the medium the wave is propagating through. The (complex) ratio of E to H is called the intrinsic impedance of the medium, and for lossless media, it's always a purely real number (about 377 ohms for air or free space), meaning that E and H are in phase. Only when propagating through a lossy medium are E and H not in time phase, and then the maximum phase difference is always less than 45 degrees.

In any version of EZNEC including the demo, you can see the value of the intrinsic impedance of nearly any medium. Select a real ground type, click Ground Descrip in the main window, and enter the conductivity and dielectric constant of the medium. (To simulate free space, enter a very small number for ground conductivity, and 1 for the dielectric constant.) Then open the Utilities menu and select Ground Info. Among other things, it shows the intrinsic impedance of the ground medium in polar form. The angle of the impedance is the time phase angle between E and H of a wave propagating in the medium.

If I understand this correctly, a field arrangement with E and H in time and space quadrature is not propagating energy, but rather energy exchange.

In very close to an antenna, the time phase relationship of E and H may be close to quadrature due to the inductive or reactive field close to the conductors, but that changes eventually to 'in-phase' in the far radiation field in free space (as the induction field components decay more quickly with distance than the radiation field components).

If that is the case, the complex value of E/H varies from very close to the far field. I have seen plots of E/H vs distance that treated E/H as a real number, but I suspect that it is more complex when all of the components of E and H are included.

Thoughts?

Owen

i tried a few combinations of audio high pass/low pass and different
ssb in each ear. there are some interesting effects you can get that
way that give you spatial effects as you tune across the band. you
can get the feeling that the signals come in one ear and out the other
as you tune across them... interesting once you get used to it on cw,
but probably not much use on other modes.

Owen
By observation the E and H fields can be seen as a tank circuit where
all vectors are accounted for so that
one follows the notion that energy cannot be created or destroyed plus
the other laws of Newton.
When we stray from that scenario we get into new theories or
imaginations The moment we stray from boundary laws one is coersed
into thinking like somebody of a lesser nature than past masters who
determine phenomina from observation that is matched by known
principles. How on earth can we relate to near fields and far fields
if we haven't decided what the media concists of. My approach was to
stick with the laws of Maxwell which dictates static and dynamic
fields where all forces are accounted for, which shows that gravity

can only be negated by the use of Newton's laws. Thus my foundations were not built on a layer of sand but what is accepted via Maxwell's laws. In other words, the laws of Maxwell points to the presence of particles when dealing with fields and displacements by virtue of the units used. There are lots of things that exhibit properties of other materials and thus by observation can be compared to other things in action, but they should never be considered as one and the same unless they are matched in their entirety. Particles and waves
have lurched beyond science by considering them to be one and the same purely by action and not by substance.
If one is going to discuss energy exchange as with inductance and capacitance to determine relative phase angles , fields etc one cannot stray from the tank circuit
observations.

Faraday knew what ever reached a receiver
had to be in either voltage or current form
The Farady cage works by the separation of charges which cancel and
thus the only thing left is voltage and current which is what the
receiver requires.
Since it is established that we can separate charges or fields the
only other thing that can be done using the same logic is to ADD the
charges or fields via a collision. Thus voltage and current does not
come into play and where collision produces what..." light."!
Note: Faraday used the notion of a charge carrying particle where the
charge was evidenced by the capacitive and inductive field content
which some would say is exactly that which left the transmitting
antenna but in reverse.Since a static field can be made dynamic such
that Maxwell's law applies the idea of particles still stands.
When the fields collide they must meld into one and not shatter
otherwise you have produced a mechanism that increases the speed of
light which is a proven by various observations. All of the above is a
natural progression from gaussian laws of statics in a arbitrary
border which is then made dynamic. No new laws required just the use
of accepted laws from the masters on whose shoulders we stand.
I welcome pointers as to where any of the above strays from the laws
of the masters
upon which classical physics is based.
All the above is logic that any student can align with that explains
radio from first principles that are known.

John, the laws of Maxwell contain only distributed loads thus actual
loads have to go thru the canceling process leaving only the
disturbance at the bends unaccounted for.
Cheers
Art

You are really good, Art. How do you keep it up?

You make new and fresh nonsense up with very many of your posts. Not
every one, but you do have to carry on your themes after all.

Still, it's quite an effort you put into it. How do you continue to
make almost no sense? That's really tough. I mean, even random chance
would say you occasionally have to be realistic.

I think Google will tell you that the earthquake you refer to was at
Madrid in Missouri, not Illinois.

As an engineer can't afford to act on theories alone
only those that have already be established.
In other words I can act on a full picture made of jigsaw parts but
not a partial picture. Therefore one must deal with fully melded and
interacting parts that are consistant to reality. Thus I adhere to
classical physics and factual observances or laws without straying
from the path I have chosen from interconnecting parts.
Quantum theory is based on probabilities and associated math. Any body
who has been to the race track knows that this form of thinking has

its fallacies thus probabilities has moved towards string theory. I stick to classical physics as they have a history of success with the laws that they have established but unfortunately physicists have corrupted the language of observances. For instance we had a discussion on Leptons, colour etc. Physicists recognise that colour as the rest of the world knows it as a means of separation of its observed actions instead of labelling it lepton1 or lepton 2.Same goes for hadrons, they actually could be a single type particle but physicists label them by the action that they exhibit on observance. Why do you think that the idea of a mad scientist hangs on to this day. They did similar things with respect to waves which in their world has nothing to do with water, tides e.t.c.
So for me there is merit in sticking to points raised by classical physics since they are tried and true
under examination and have not exploded by categerizing particles by a particular observation.
After all, both a dog and a cat have a tail they can wag but the real world can have the same observation of different entitiesand vica versa.
What I desire the most is for somebody to challenge my statements based on documented observations and laws bearing in mind that the written word comes after factual examination and not before.As yet nobody has pointed out a fallacy that is in conflict with presently known laws, and I mean nobody. If there is a conflict then I will discard all. But remember, I do not make computer programs on radiators but they all confirm the presence of particles and equilibrium and I have had no way of manipulating that to conform to my thinking. They show that maximum radiation is obtained when material resistance drops to zero and radiation rises to a maximum via current flow outside the member to elevate particles at rest on the surface. I couldn't possibly string some thing like that as a joke or by not taking my medicine.

Very true. However the Ohio river and the Mississippi river join not
far away from the earthquake epi centre that it forced both the rivers
to flow backwards making new channels, placing vessels in areas where
present day waters do not flow and of course flooding every where. I
checked out the map and the actual river town was in Kentucky no less
because the "dual carriage way" I traveled on wandered over the border
for a few miles.
Cheers and beers.
By the way Bush was an addict
for M and M's as he was sure that it really was a "W" that was

Hi John,

It is deceptively simple, and excruciatingly difficult to both build,
or to describe. That is the wonder of "meander." Just by the English
alone, it should inform you that how do you duplicate the meander of a
drunk's walk? It's like trying to gracefully do a toe-to-heel amble
20 meters along a 12 meter long sidewalk. Imagine trying to follow
turn and distance instructions at the same time while the constabulary
are grading your performance.

There is no defined path length to the drunk's stagger, and there is
no defined length to a 7.1MHz Meander dipole. If it doesn't tune up
after you build it, then you did it wrong. In other words, it's an
academic joke.

Can't get much clearer than that.

Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

I recall one of my RF neighbours (VK2BBC) telling stations he was using a
BTMD. That certainly (in those days) sparked a bit of interest, some new
type of fabulous antenna? What was it?

The acronym was for Bent Twisted Mangled Dipole.

Same concept, different implementation!

I believe that's correct, but there's no medium in which that would take
place -- with a plane wave at least.

>
> Thoughts?

Yes, E/H varies a great deal in both magnitude and phase in the near
field. The intrinsic Z describes only the E/H ratio of a plane wave
propagating in the far field. This can be easily investigated with NEC,
EZNEC, or any modeling program that provides near field results.

Incidentally, the physical orientation of E and H, and I believe their
time phase, can be quite different when bounded by conductors as in a
waveguide.

> Thank you for your time.

You wrote:
"I begin to appreciate a comment made by a fellow radio amateur and technician that antenna theory was 15% science and 85% black magic! "

But in your paper is 85% of science.

Next you wrote:
"Figure 2-3 is a simple picture of an E field detaching itself from an antenna. (The H field will not be considered, although it is present.) In view A the voltage is maximum and the electric field has maximum intensity.
"

That is all. Radio waves are simply the alternate electric field. You should add only that in the and of the dipole the voltage is doubled (at least).

At the end you wrote:
"For myself, I like the humbling fact that despite building our modern technology and economy to large degree on the manipulation of electro magnetic radiation; when it comes to understanding exactly what in fact it is, there still remains some uncertainty and mystery!"

Not always it was a mistery. In the radio history the radio waves were always the electric waves.
Maxwell's hypothezis (EM) was a proposition for the transverse waves (to explain the light polarization).

Now we can produce polarized or not polarized electric waves (by proper arranged polarity).
Polarized light is emmited from dipoles. In nature no monopoles.

Hello,

I assume that you talk about meandering like the zig/zag pattern on a viper or the pattern of a sidewinder. At other frequencies, yes I do have.

Meandering increases the inductance per unit of length, so the propagating wave slows down. This results in a reduction of resonant length.

The zig/zag wire pieces do, however, not contribute to the far field radiation. Given the same feed current, the meandered dipole radiates less then the full HW one, so the radiation resistance goes down. When your dipole length is about half of the full size length, feed point impedance goes down with almost factor 4.

When you experience good VSWR in a center fed short meandered dipole, you can be sure to have losses.

Best regards,

Wim

Peter, the moment you deviate from the ARRL version of intersecting
fields and refer to waves is when you are going to lose your audience.
Maxwell specifically refers only to two properties inductive and
capacitive both of which can be seen as fields.
ARRL then states that these two fields interact at right angles to
each other which is an interaction of current flow ACROSS a capacitor
which is created by the displacement current. Note that waves are not
even being mentioned. This is exactly the mechanism of a particle in a
crt where the particle collides with a screen and the point it
interacts with the screen is governed by two vectors. The only
difference between radio and the crt beam is that
tho both beams are particles , rotating modulation is only imprinted
on the particles occillations or "spin" to form a information carrier
for radio purposes. It is still a closed tank circuit which is the
propelling engine at the end of all transmitters, except in the
radiation cases the closed circuit crosses over itself by passing
sideways thru a capacitor created in the form of a eddy current
created by the reactionary displacement current flow
The idea of using the "wave" term is a carry over from the old days
where the aether was viewed as a viscous soup which has now been
discarded and replaced by a cloud of free electrons swerling around
looking for a diamagnetic place to rest and where the volume of
electrons is more than the available places to rest. Why a diamagnetic
place to rest? Because diamagnetic means that there is no residual
magnetic content within the resting place medium.
So Peter, your audience can align visually with the idea of a crt
and a beam created by a combination of capacitance and inductance
which provides a straight line trajectory which is a central part of
radio, and gets away from a viscous

water wave movement that does nothing to infer a straight line projection or the energy sinosoidal interaction created by a tank circuit or indeed a pendulum.

Here is the drawing of the cat:
http://library.thinkquest.org/18160/electriceasy.htm

>The wireless is the same, only without the cat."

There is a small difference. If instant of the cat (wire) is an insulator
(aether) in it flows the displacement current. The current is strong when
the capacitance and the frequency is big. It is easy to achive the huge
frequency but for this you must use the modulation.

Qrz forum has a new posting that states the USN
changed their antennas on the west coast to those tipped from the
horizontal for superior results. This is 60 years ago before the
advent of antenna computers. I would like to think that they saw the
advantages of using two vectors as opposed to just the single one for
gravity, which in a way confirms the diversity antenna shown on the
unwinantennas page which is sensitive to multi polarities. Ofcourse
many on this net will disagree in order to avoid change.
Cheers

This is news to me! Can you give me a reference ?
This clearly suggests that a twin wire formed in a closed circuit
helix cannot radiate in the far field when it clearly can regardless
of slow wave. If the dipole is clearly in equilibrium it cannot fail
to radiate but then everything depends on the presented aparture and
what medium it is operating under, such as a submarine at some depth
in sea water versus fresh water. I have found that such arrangements
start out at over 100 ohms and then gradually dampen down to 50 ohms
when you start to exceed twice the full wave length and it comprises
of a fully connected electrical wire circuit

A fine example of a meander circuit would be a fractal arranged in
full circuit form

Hello Art,

The zig/zag or square wave pattern is frequently used in planar structures (PCB antennas or metal on plastic/paper).

Regarding your request for references, look at UHF (800-900 MHz) RFID tags/transponders (TI, Alian, Rafsec, Feig, Deister, Sams, etc). They use meandering to shorten the overall length of half wave resonating structures. The radiaton pattern still matches that of a dipole, so negligible radiation in axial direction. As you are a ham also, it is not too difficult to prove this yourself.

To get some axial sensitivity, the width of the structure should no longer be << overall length of structure.

Best regards,
Wim

For me. no one does a better job than Dr. Frederick Emmons Terman who wrote on page 1 of "Electronics and Radio Engineering":
"Electrical energy that has escaped into free space is in the form of electromagnetic waves. These waves, which are commonly called radio waves, travel with the velocity of light and donsist of magnetic and electric hields that are at right angles to each other and also at right angles to the direction of travel."

The rest is in the book which should be consulted for a complete definition.

Best regards, Richard Harrison, KB5WZ5

Maxwell proposed EM to explain the polarization of light.
Now the radio waves are or are not polarized.

Wiki wrote: " FM radio
The term "circular polarization" is often used erroneously to describe mixed
polarity signals used mostly in FM radio (87.5 to 108.0 MHz), where a
vertical and a horizontal component are propagated simultaneously by a
single or a combined array. This has the effect of producing greater
penetration into buildings and difficult reception areas than a signal with
just one plane of polarization. This would be an instance where the
polarization would more appropriately be called random polarization (or
simply unpolarized). See Stokes parameters."

Why "erroneously"?

Are the radio waves different than light?

Yes, as light waves are much higher in frequency than radio waves but, in most ways they are identical. As an example, cross-polarized receptors for both light and radio waves suffer greatly in receptivity.

radiation."

My take is slightly different. The complete antenna can be considered as
made up of infinitely small pieces, each of which contributes to a
wector sum at a distant point in the far field depending on the current
in the tiny segment and its position.

Hello all,
I do appreciate the input, seems like its not such a good idea!

Just to clarify the actual construction details, the configuration would be in a dipole.

The 1/4 lambda wire would be wound on a form which has slots cut into the periphery of an insulator to accommodate the wire and the form would be 300mm (12") in diameter, the wire would be wound from top to bottom of the form until all the wire is wound on the form. I envisage a 75mm (3") gap between each slot, maybe more depending on the distance between the circular insulators, around 1500mm (5 ft).

Hopefully you can picture what I was going to build!

John
VK2KC

There would be two of these and

And that's exactly how antenna modeling programs calculate the field --
except that the antenna is broken into a finite number of pieces rather
than an infinite number. As long as the current doesn't change much over
the length of one piece (or "segment" as called in antenna modeling),
the result is very accurate.

That is my experience too. Space diversity requires 2 or more antennas and receivers. One antenna can serve separate receivers which are connected to cross-polarized feeds using a single reflector for polarization diversity.
Or, multiple receivers can be used on a single receiving antenna, but transmission of more than one copy of the desired signal is required, This is how frequency diversity is usually achieved. Two copies of the same program may be modulated on the same carrier if it is shown that the medium treats the sidebands differently so that when one is treated badly the other may be solid. I`ve seen this done with selection of upper or lower sideband from a double sideband transmission.

Thanks. It's an unusual experience when someone actually agrees with me.

Part of the problem is that HF and microwave diversity have different purposes and therefore different methods. I'll try to describe some of these (until the epoxy dries and is safe to handle).

For example, the common Wi-Fi 2.4Ghz access point, uses diversity to mitigate the effects of frequency selective fading. With two antennas, one receiver, and a PIN diode switch, the access point normally has one MAIN antenna selected. However, when the error rate climbs to the point where the MAIN antenna is hearing garbage, the PIN switch selects the AUX antenna in the hope of an improvement. With frequency selective fading, the MAIN antenna could easily be sitting at a location, where the direct and incident paths from the client radio are 180 degrees otto phase, and therefore would cancel. By switching to the AUX antenna, the assumption is that it is not located in a place where the signals cancel.
<http://www.cisco.com/en/US/tech/tk722/tk809/technologies_tech_note09186a008019f646.shtml>
<http://www.commsdesign.com/design_corner/showArticle.jhtml?articleID=16501888>
<http://www.commsdesign.com/design_corner/showArticle.jhtml?articleID=16500279>

For VHF/UHF, a form of diversity that is very commonly used is a receiver voting system. These are heavily used by municipal services to cover wide areas with HT's. The HT can easily hear a single central dispatch transmitter, but the return TX power is limited, requiring multiple receivers at difference geographic locations to cover a city or county. For such systems, remote receivers are located at various locations. The backhaul returns the audio and data to a central location, where a voting system equalizes the backhaul delays, determines the best SNR, and provides the dispatcher with the best possible receiver audio or data. There are various patented schemes to make the SNR selection. While not normally considered a diversity reception system, I consider it to be a form of diversity.
<http://www.repeater-builder.com/tech-info/votingcomparators.html>

For HF, the problem is fading caused by atmospheric and ionospheric phenomenon. There are several types of fades (flat, frequency selective, multipath, Faraday rotation polarization change, absorptive, fast, slow, etc). Some of these are detailed in:
<http://en.wikipedia.org/wiki/Fading>
The assumption is that for most (not all) types of HF fading, geographic separation of the antennas will result in one of the two antennas being in a location where the fade is minimal. In order to utilize this advantage, some manner of voting system needs to be implemented to decide which antenna is best. This is usually done with two receivers, but can be done with a single receiver and an antenna switch, if one is willing to tolerate some data loss when the receiver is switched to the wrong antenna.
<http://www.navy-radio.com/rcvr-div.htm>
(Also search for "dual diversity HF reception")

Locating the two HF antennas at a single location has some benefits when dealing with polarization diversity, but is generally a loser when dealing with most of the others, where both antennas (and both polarizations) are likely to simultaneously experience the same fade mechanism. For such contrivances, I suspect it might be equally effective to setup the HF antenna for circular polarization.

Ok... the epoxy is sorta dry.

So in most ways yes.
Radio waves from the dipole are polarized. Does it mean that light is
emitted by a dipoles?

We can shield the one end of the dipole. Are such waves polarized?

Why the dipoles exhibit the directional pattern?

Are the ansfers in "Electronics and Radio Engineering"?

In antennas are the standing waves. In a long wire antenna are many nodes.
Does anybody calculate the contribution from the nodes only?

Hello Richard,

Agree with the basic principle of (far) field calculation. Regarding
meandering or helical wound:

The longitudinal components reinforce each other, but the lateral
components (zig/zag parts), change direction each time. Therefore the
resultant field (vector sum) is negligible with respect to the field
from the longitudinal components.

It's not the best idea, but don't think it's not a good idea. If you use a broad definition of meander, you can have drooping ends, of one time I made an antenna that was sort of "Z" shaped.

It's making antenna for the space you have available.

Sounds like a form of slinky antenna to me. You wouldn't end up with a quarter wavelength on each side, it would be less due to inductance.

What frequency are you looking at here?

Hi Richard,

The discussion of heat is more a metaphysical concept because it is confused by our senses.

Entropy demands that everything inexorably cools by dissipating its energy (heat) into the void of cold space. Hence, everything radiates (and yet we spend very little time writing about it, except for Art). A good deal of this entropic radiation is like waiting an infinite time for a circuit with infinite-1 Q to stop ringing.

The sun burns bright in the cosmos, but the greater part of the cosmos is unheated by the sun even though all of the cosmos is illuminated (radiated) by the sun.

Direct observation 1: Put two plates out in the noon sun but undisturbed by the motion of air. One plate of metal, the other of glass. Which gets hotter? Same amount of radiation from a known heat source, but clearly different results in heat.

Direct observation 2: Shine (radiate) an IR LED onto the back of your hand, or onto your forehead (an excellent heat detector). What do you feel? At some IR wavelengths, your head is as translucent as an architectural glass brick.

Hello John,

There are many options for your frequency range.

Try to get some ferrite rings that tight fit around the coaxial cable and that have high impedance around your frequency. When you have specs (from the ferrite you use) this is the easiest one that doesn't require any tuning.

connect the feed cable to a solid ground at 0.23 lambda from its end (where the loop is). The low common mode Z at the short results in a high common mode Z at the end (where the loop is). two strips of about 0.22 lambda can also serve as a floating ground.

you can make a bazooka type choke (about quarter wave sleeve around the cable). Best is to have lots of air between the sleeve and the coaxial cable. This one requires some experimentation as the actual length depends on the dielectric around the cable also.

When your loop impedance turns-out to be high, your balun must be better as the common mode voltage component increases with high impedance balanced antennas. I see you are working on a full wave loop, this one is not high Z (below 200 Ohms).

Good luck with the loop measurements,

Wim

This illustrates a classical confusion between heat and temperature, probably aggravated by our use of "hot" as a description of temperature rather than heat. Heat is energy. Absorption or transfer of heat results in a change in temperature. "Hot" (high temperature) objects radiate more heat than cold objects. The more heat an object, such as a plate, absorbs, the higher its temperature. Once this basic distinction is clear, a lot of the mystery disappears.

There are, of course, other mechanisms of heat transfer other than radiation, namely convection and conduction. But heat transfer has the same effect on temperature regardless of the mechanism.

When doing experiments with the sun's rays, you sometimes get non-intuitive results, because there's a lot of energy (heat) at wavelengths we can't see, particularly at the ultraviolet end. The reflective or absorptive properties of an object aren't necessarily the same at infrared or ultraviolet wavelengths as they are at visible wavelengths. For an example, you can't see the difference in my skin when coated with sun block or not. But there's sure a difference in energy (heat) absorption!

Having been in the navy on both coasts, years ago before the advent of
antenna computers, (alert: reality intrudes here) nothing is vertical
or horizontal aboard a ship.

We had absolutely no antennas that were "tipped from the horizontal" -
whatever that means.

There are also complications about temperature when referring to solids,
liquids, and gases. The "temperature" of even a weekly ionized plasma
is quite high (e.g. 11000 K per eV), but that more to do with the
velocity of the ions and the mean free path. There's not much mass
there, so the "heat" is small. That is, even though the ionosphere is
"hot" in a temperature sense, it's not very "hot" in a sensible transfer
of heat sense.

BTW, I think the sunburn is not from thermal absorption, but from
photons with enough energy to make the reaction go. The total energy
in the UV of sunlight is MUCH lower than the total energy in the visible
range. The power spectrum of sunlight is pretty close to the spectral
sensitivity of your eyes (which evolved that way to match, I would think).

At least one reference says that sunburn is a direct reaction to DNA
damage from UV photons. Melanin protects because it absorbs the UV and
turns it into heat.

Hi

Which is the name of a feeding system in that the driven element of a Yagi (for example) is split in two parts, and two pieces of isolated wire are introduced in both sections of the split driven element? (to find it in the Web)

Thank you very much in advance.

Miguel

A good graph of sunlight power density vs wavelength can be found at
http://en.wikipedia.org/wiki/File:Solar_Spectrum.png. Comparing areas of
various graph sections shows that the UV part of the spectrum contains
maybe 1/5 the amount of energy as the visible part -- plenty enough to
embrittle plastics and fabrics and sunburn skin. But the infrared energy
-- invisible to our eyes -- looks to be at least equal to the visible
energy.

Some people like to view electromagnetic waves as photons. I find waves
easier to understand, but each to his own.

My explanation was simplified. There's also latent heat or heat of
change of state. For example, if you apply heat to ice, it'll warm up to
0C, but stay at that temperature in spite of the heat input until it
melts. The heat (energy) goes into converting the ice to water instead
of raising the temperature. After it all melts, continued heat
application will of course raise the temperature of the water.(*) Until
it reaches the boiling point, that is. Then the same thing happens again
-- it stays at 100C until it all boils. If you confine the resulting
steam, adding heat will raise both its temperature and pressure after
the water is all converted.

(*) That's why people experienced in cold weather outdoor activities never eat unmelted snow for water when there's any danger of hypothermia -- it takes about twice as much heat just to melt 0C snow into 0C water as it does to raise the temperature of 0C water to body temperature. In other words, you use up 3 times the energy eating 0C snow as you do drinking 0C water.

It's not obvious how you'd be able to effect an impedance match with this method. To be able to match an arbitrary impedance, you need to be able to adjust two things which are at least partially independent. For example, a gamma rod length and series capacitance. With this scheme, you've got the length of the wires inserted in the tubes. What else can you adjust? Wire diameter will give you some variability, but not an awful lot, and it isn't easy to vary.

The plastics degradation is definitely an "athermal" effect (because
adding carbon black to the plastic inhibits it, but doesn't change the
absorbed power very much.

But..
note that the scale is in wavelength and the energy is "per nm" (because
that's how spectrophotometers work). the photons have less energy at
lower wavelength. (or, you could plot it in frequency, and then look at
the watts/Hz to integrate)

If you look at power spectral density (e.g. watts/hz) it actually peaks
up around 1000 nm (near IR). The Wien displacement law says that 5250K
peaks up at about 550 nm, but the power spectral density at 550nm (545
THz) is about 2/3 that at the peak.
By the time you get to 350nm (857 THz), the energy per hz is about 10%
of what it is at the peak (at 950nm)

Running a quick numerical integration... (multiplying the power spectral density every 50 nm by the frequency range).. I get 0.166 for all wavelengths shorter than 320nm, 2.09 for 320-670, and 3.6 for 670-4000 nm (there's a missing integration constant, so the numbers have some scale factor, but the relative amounts should match..)
for the band around 400nm, I get .26 and for the band at 550 about 0.34 and for around 650 about .32... Yes, it peaks at 550 nm as expected.

UV radiation has migrated awary from electron/atom issues to
molecular/ionic bond issues. Calling it "athermal" seems to be
returning the discussion to the metaphysical.

Without going into the math, it seems like you disputed a figure you
then discover "as expected." What was the dispute? What wasn't
expected and then came as a surprise?

All in a thread about temperature and heat..
That was actually in response to Roy's original comment
"When doing experiments with the sun's rays, you sometimes get
non-intuitive results, because there's a lot of energy (heat) at
wavelengths we can't see, particularly at the ultraviolet end."
and my response that there actually isn't much energy in the UV end.

Roy commented about sunburn, and I pointed out that the mechanism in
sunburn isn't thermal (and this is important to folks who worry about
RF exposure limits and regulatory compliance.. thermal effects have one
biological result, athermal effects are another..)

My comment was that sunburn (and Roy's example of plastic degradation)
are due to the energy of UV photons actually causing a chemical
reaction, as opposed to making something happen because of heat.

Roy's comment was about the amount of energy in the non-visible bands (presumably in response to my comment that human eye sensitivity tends to match that of the solar spectrum/ 5250K blackbody), and he cited the very commonly seen graph in W/nm, with a scale linear in nm.

My point is that in the RF world, we tend look at power spectral density in terms of W/Hz, so when you are looking at the graphs (with a linear scale of wavelength or frequency, as appppropriate), a visual estimate of the "integrated area under the curve" can be misleading. If you plot the same data, but in W/Hz, and with a scale linear in frequency, you get a very different looking graph.

Try it.. the equation is of the general form
power density (per hertz) =
constant1*frequency^3/(exp(constant2*frequency/T)-1)

power density (per unit wavelength) =
constant1/lambda^5 * 1/(exp(constant2/(lambda*T))-1)

>
> Roy Lewallen, W7EL

To be honest, I'm not sure which one is appropriate to integrate. In theory, if you're integrating between two limits you'd use the expression that matches how the limits are specified..

That is, if you wanted to get the energy between 350 and 600 nm, then you'd use the energy/nm

OTOH, if you wanted to integrate between 470 THz and 800THz, you'd use energy/Hz.

they "should" come out with the same answer (especially in the limit of actual integration with respect to d(nu) or d(lambda)).

It's probably only when you do a rough and ready numerical integration (or do it by eye off the graph) that it makes a difference.

Actually, it's kind of interesting that you brought it up, because, like you, I'd always seen the W/nm with a linear scale in nm graphs...

I have not seen it done, and can't imagine wide application.

The technique presumably is to insert a (lossy) capacitive reactance in
series with the feedpoint, and such that the reactance decreases with
freqeuency, thus exacerbating the natural feedpoint impedance change.

Hi, would anybody know (or like to know?) the "secrets" hiding in the pvc tube antennas like Dressler ARA-500, 900, 1500, 2000 LF-Engineering H800, etc. What kind of element is used as antenna, also the config of the preamp. and the semis used? Their overall efficiency? I know my questions are many fold but still I'd like to know. Thanks to All. Just Curious.

I think it was Mosley that used it in their Classic 33 beam. I don't recall
exectally how it was made, but the driven element was in two insulated
pieces. Then a piece of coax (it may have been just the center part with
the braid stripped off) was placed in the driven element. Part ran inside
one element side and the other part ran the other way I don't think there
is any direct connection to the driven element.

I am curious about your statement. You say "insert a (lossy) capacitive reactance in series". Why would a braidless piece of coax inserted in a tube have significantly different loss than the intact coax of that length?

I've made matches made that way for decades that ran at full or near full legal limit on 6m. I'm pretty sure that any significant loss would have shown up as dripping plastic. The matches when taken apart after years of use show no sign of heating.

Tom,

My use of "lossy" was to remind readers that capacitive reactance
obtained by using such a transmission line element is a relatively lossy
'capacitor'. For example. an o/c stub of RG213 for a reactance of -10
ohms at 144MHz has a resistance of about 0.1 ohms, or a Q of about 100.
That is not a huge loss, but quality capacitors achieve much higher Q
than that.

So, I don't know why one might use such a thing in a driven element,
introducing say 0.2 ohms of resistance which consumes about 0.4% of the
power if it was a R=50 feedpoint, when a similar reactance could be
obtained by a slight shortening. The purpose is probably not for
frequency compensation, it works the wrong way.

Is the loss significant, not really in this case, and it won't melt the
PE, but TL derived capacitors are relatively lower Q.

The units would cancel unless that is your intent - but I am still
stymied by what is being sought by these elaborations.

>
>they "should" come out with the same answer (especially in the limit of

Hence my question about the significance of changing domains when
either integration must, ultimately, come to the same thing in power.
None of this is currently being expressed in energy (a term being
commingled with power), which for optoelectronics would be eV.

This would raise a curious representation of a third domain with
re-rigging the wavelength/frequency scale into the appropriate energy
scale of eV vs. power. The solar radiation spectrum would thus span
(left to right) 5eV to 0.5eV.

Where is this leading?

For what it's worth...

I've often found it useful to consider alternate ways to think about
things. In this thread, there have been some comments about electric
fields, magnetic fields and electromagnetic fields. So, I ask: how
do we measure fields? As far as I know, it's by their interaction
with matter: we observe how an electromagnetic field accelerates
electrons, for example. Do we have any way other than by observing
how a (E, M, or EM) field interacts with matter to measure a field?
If not, does a field _necessarily_ have any physical reality, any
reality beyond a mathematical model to explain what we observe?

I suppose some here won't be ready to contemplate this in any depth,
though others may find it enlightening.

One might say that radio is the practical use of the observed physical
effect that accelerating charges in one place leads to free charges at
distant points being accelerated, in a manner we're able to describe
pretty accurately, so far as we know now, with our models.

Cheers,
Tom

I'll take the .4%. I'll take 4%. It's a bulletproof easy way to make a
gamma match. I've never had one fail, and I've made quite a few.

And you need to define where you think lossy starts, because nothing
that we can afford to use isn't, and true room temperature
superconductors still aren't available.

And I forgot to address this.

Because .4% is meaningless and the change to a slightly less lossy feed
method would contribute nothing useful for the effort.

Because the effort with your method is that I would have to trim an
element clip by clip instead of simply sliding things at the match.

Sorry, but I thought of another comment. :)

Length for length, a 50 ohm feed yagi has already lost much more than .4% when compared to a well designed yagi on the same boom in the 20 to 25 ohm range.

I'm speaking of .6 to .8 lambda and up yagis.

Hi Tom,

You ask if we have "any way other... [than where a field] interacts with matter." In a side thread, there is the discussion of heat. Heat is a quasi-particle which means it does not exist as a physical entity, but it acts like one (shades of photon duality). Heat is wholly without matter, but in the whole absence of matter there is no such thing as heat.

As to the remainder of the quote "to measure." This demands physicality and your statement is self-negating in its plea.

If we rewind to the beginning of the plea, "observing" is a physical interference described by Heisenberg. The bookends of your plea are, then, doubly negating. That or (and here the thread returns to metaphysics once again) interactions go unwitnessed - which is an existential negation.

Expecting any reports from the Cat in the Box? Perhaps through an entangled cat?

On the first day of the first class of Electromagnetic Fields, I asked the professor (Carl T.A. Johnk, author of _Engineering Electromagnetic Fields and Waves_), "What is an electromagnetic field?" His answer: "It's a mathematical model we use to help us understand phenomena we can observe and measure." And I see that in the second paragraph of his book he writes "A field is taken to mean a mathematical function of space and time." I've been satisfied with that definition.

Wiki wrote: "The field can be viewed as the combination of an electric field
and a magnetic field. The electric field is produced by stationary charges,
and the magnetic field by moving charges (currents); "

But what produce very slow charge?

Next Wiki weote: "From a classical perspective, the electromagnetic field
can be regarded as a smooth, continuous field, propagated in a wavelike
manner ;"

It is important to know that Maxwell's waves are rotational (oscillating
magnetic whirl).

Alternate electric field also propagate in a wavelike manner. But here to
and fro (no rotations).

The fundamental question: Are radio waves a simple electric waves or the
very sophisticated Maxwell's waves?

No secrets, just a short and probably simple antenna and low noise amplifier. The antenna is likely to be a simple monopole which would be no longer than about wavelength at the highest frequency to ensure low angle omnidirectional response. There's no practical way I know of to define the efficiency of an active antenna. Other than amplifier noise figure, what would separate a good active antenna from a bad one would be the dynamic range of the amplifier -- poorly designed ones would be prone to overload and spurious signal generation from strong signals.

ALL radio waves can be described by maxwell's equations, both simple
linear polarized ones and circularly polarized ones.

The fundamental question is really how can we describe this "wave".? A
wave of what "water",
A wave of "water" traveling towards a beach.
Is it water we are really trying to describe or what?
Water has a "skin" on its surface , a skin that encasulates it like a
bag , container or a boundary!
Nothing is clear when describing a "wave" with respect to physics, as
it is just a "F" word to substitute an unexplainable in a psuedo
description
There is no agreement what so ever as to what a "wave" is so there
cannot exist a description of what radio "IS", "IS"!. Physicists
acknowledge that radio is some thing that is unexplanable leaving just
hams to fill in the unexplainable about radio and to deny the
explanations made by others.
What we do have is a string of mathematical equations all of which
interlock which are a result
of observation and seamingly reasonable deductions. Maxwell deduced b
y examination of units used that a portion of his formula was also a
mathematical explanation of elevation and acceleration but no
description of what! A physicists
named Gauss who provided a lot of Maxwells tools
used Newtons laws to establish boundary laws where it can be seen that
mathematically a clump of static particles in equilibrium could be
made
dynamic by adding a time varying field while retaining equilibrium
meshes with Maxwells equations on radiation. So who on earth descided
to interject "waves" into the discussion and why?
And what experiment was performed that dictated its inclusion in the
subject of radio or radiation that has put a screaming halt to a
sustainable explanation of same for more than a hundred years
where other dreams have come to fruition by utelizing the human brain.
Is it the ham population
that is responsible for the lack of advances in the advancement of
science by denying the inclusion of particles as the basic matter
involved in elevation and acceleration (displacement) as implied by
Maxwell's equations, preferring instead to use 'water' and 'waves' to
describe the science to the non initiated.

In Maxwell's displacement current were charges (electricity).
In the space no charged bodies.

Charged particles can move at any speed from 0 to c and always produce the
electric field. Why not?

Maxwell's waves are transversal. It means that something oscillate around
the axis of rotation.
Linear polarization means thet the rotating oscillations are in the one
plane.

In Maxwell's Hypothesis.

Wiki wrote: " FM radio
The term "circular polarization" is often used erroneously to describe mixed
polarity signals used mostly in FM radio (87.5 to 108.0 MHz), where a
vertical and a horizontal component are propagated simultaneously by a
single or a combined array."

It seems that radio waves are the electric waves.
If yes, the light is also longitudinal.

Water waves are described by Stokes:
http://en.wikipedia.org/wiki/Stokes_drift

Maxwell did it. Maxwell described it in English. The equations wrote
Heaviside.

The dynamic particles are waves. The Gauss time varying field is the
longitudinal wave.

The water and waves are usefull in schools. Everybody can see.
Light, radio waves and sound waves are analogous in the all details.
Sound waves and radio waves are not visible but many experiment was done.

From memory the ARA-500 (50-500MHz) used a fat printed circuit biconical style dipole with a broadband balun feeding something like a BFT66 bipolar transistor RF amplifier with ferrite transformer derived negative feedback (Similar to a broadband pre-amplifier design originally published in the German 'VHF Communications' magazine sometime in the 1970's). The later versions used FETs or broadband amplifier MIMIC's of various types and a strange helically wound antenna element constructed from foil tape.

As long as you can achieve reasonable impedance matching to the active device across the required frequency range, and an amplifier noise figure which is better than the atmospheric noise level which can be received on the physically small antenna element, then it should work as well as (or in some cases better than) a full sized antenna. However this is a tall order, as strong signal handling is the main issue with low noise amplifiers, especially when used in a broadband configuration in the presence of strong local signals (usually broadcast stations).

A good design of balanced HF active antenna (100KHz to 50MHz) can be found on the link at the bottom of this web page.

you mangled the replies so badly that i couldn't even follow what you were saying. light and radio waves are the same thing, as are gamma, infra red, x-ray, etc... all the exact same phenomena explained very well by maxwell's equations. scientists for 100 years have been unable to come up with anything better, you aren't going to by your misguided assertions that have no mathematics or experimental evidence behind them.

sound waves and water waves are VERY different things. while some of the equations take the same form because they share sinusoidal repetition properties, the underlying physics is VERY different. you have to abandon the analogies you learned in elementary school and learn the proper physics to understand why electromagnetic waves are not like sound or water... start with this, why can you polarize light or radio waves but not sound waves?

yes, to within many, many decimal places... if they did not agree to
within the limits of measurement then someone would have had to make a
new theory to explain the difference.

maxwell's equations do not describe particle motion, they describe electric and magnetic fields and electromagnetic waves. as i just tried to point out to mr. b, the elementary school analogy of water waves to explain electromagnetic waves must be abandoned before you can truly understand em waves.

That depends what you mean by "without any matching property".

If the o/c stub is less than an electrical quarter wave (as it seems from the description, it must introduce some series capacitive reactance, and loss resistance, the longer it is, the higher the loss resistance.

It is not at all obvious why they would do what you described (and for Tom's benefit, I am not talking about a gamma match).

> can truly understand em waves.

I am happy about that but it doesn't help me to understand em waves or where they are involved with Maxwell. It is inbuilt in physics that we are accelerating a charge where acceleration demands mass. But there is no continuation of explanation beyond that point. Every theory since classical has broken down and we are now in the superstring theory while at the same time trying to collide the smallest particle on earth which determines the speed of light. You definitely can not involve acceleration without mass, and gravity can only be canceled by a reactionary vecto r being involved and you cannot have a straight line trajectory without two vectors representing gravity and its associated spin. Frankly, we should start again using the basics of Newton as used by Maxwell and then backtracking to the time of Einstein by supplying the relationship of static and dynamic fields so that frausteration did not drive us away from former progress in physics over the centuries to invent particles without mass, anti particles and acceleration of string which can take on the shape of a wave.
What startles me is the acceptance of computer programs based on Maxwell which clearly show that the radiating member must have zero resistance for maximum radiation. That radiation resistance implies that of an encapsulating substance which is elevated and accelerated by the action of displacement current in a similar manner to scrap metal sorting yards. Now I read that present particle science is retracting to the idea of a single particle being the source of the standard model and where the existing environment is creating the observences at any point in time based on the existance of matter in all cases. It is time we reverted back to the demands of equilibrium where an "equal" sign addition to any equation demands that the addition of all used in that equation must equal zero. Which is a staple of all that is used by the human race over the centuries. Not one of many theorems on radio have come to fruition with the use of integra ated solutions to satisfy the whole. All we have are totally disconnected imaginations spawned by using mathematical tricks of doubtful merit with imaginary inventions to fill in the inevitable gaps.
We only have one tool that is solidly connected to equations of maxwell and that is the computer programs with optimizer that adheres solely to the stated equation together with adherence to equilibrium. What better place exists to delve further into the Masters thoughts

rather than the manufacture of another theorem?

Have you ever seen the dipole which one end is without a cap and the other
with the huge cap (the body of the car?
The body is rather a mirror for the monopole.

new theory to explain the difference.

No such need. For the radio waves apply all knowledge for the acoustic
waves.
The monopole works like the Kundt's tube. The dipole like the two.
The directional pattern is the same for two loudspeakers like for the
dipole.

infra red, x-ray, etc... all the exact same phenomena explained very
well by maxwell's equations. scientists for 100 years have been
unable to come up with anything better, you aren't going to by your
misguided assertions that have no mathematics or experimental evidence
behind them.

Maxwell's electricity is incompressible.
Todays electron gas is compressible. Behind them is mathematics (plasma
physics) and experimental evidence.

>sound waves and water waves are VERY different things. while some of
the equations take the same form because they share sinusoidal
repetition properties,

Sinusoidal means harmonics. Real waves are not harmonics. They are rather
the chain of the solitons.

> the underlying physics is VERY different. you
have to abandon the analogies you learned in elementary school and
learn the proper physics to understand why electromagnetic waves are
not like sound or water.

Sound and water waves are the real waves and such have always the two
components (longitudinal and transversal).
Maxwell' em waves are pure transversal. Maxwell wrote that it is a
proposition.

>.. start with this, why can you polarize light or radio waves but not sound
>waves?

I did it. Radio waves and sound waves have the same directional patterns for
the same numbers, configurations (and phases).
The two waves emitted from the dipole (ACOUSTIC OR ELECTRIC) are
"polarized". You can experimentally determine the plane in which the dipole
is.

The same is with more sources.

What do you think. Is the electron a charged particle?

Maxwell assumed that the electricity is massles and incompressible.
He would be right if the electron is a charged particle.

I've been trying to understand the basics of HT radio antennas. The first part that puzzles me is the "ground" side of an antenna. Or if I can use a Dipole as an example one side of the dipole. Or if we use a groundplane the radials. With an HT are we just "doing without"? Or is this just my dumbness in action?

My second question is in asking how effective is the typical rubber duck antenna versus say a truly resonant antenna or even a 5/8th wave which tries (if I understand it) to squish the pattern down from a sphere to a doughnut so its hears and talks better out then "up and down"

In my mind I would simply like an antenna that was effective but flexable. Length is not "critical" as I plan to hang it up high on an LB harness. The idea is a rough and tumble antenna that can work in the woods on a Search and Rescue mission but will give me the very best range out (not so much up/dn)

Has anyone done any serious work with HT antennas? Is there anyone clued into how to match these properly? And has anyone looking into using spring steel (Such as Measuring tape) for the antenna as the Military uses in many of their radios?

Thanks for any thoughts on this de Jay W0VNE

With an HT, the radio and the person holding it are the lower half
of the antenna if using a 1/4 wave or 5/8 wave. And yes, a full
length antenna will trounce most rubber ducks.
A good antenna for HT's is the half wave. But I've seen the 5/8's
do pretty well even considering the problems.
A 1/4 wave is a good cheap antenna. IE: get an adapter that
converts the rubber duck connector to a SO-239. Then stick
a 1/4 wave whip in the center pin hole. Quicky 1/4 wave that will eat
most all rubber ducks. And using external ground planes, verticals
works well too.

The case of the HT and your hand are acting as the counterpoise (other
half of the antenna). There have been some efforts to improve on the
HT antenna by adding a wire counterpoise:
<http://www.hamuniverse.com/htantennamod.html>
It goes under the trade name of "Tiger Tail". There are some boring
You Tube videos describing the construction.

>My second question is in asking how effective is the typical rubber duck
>antenna versus say a truly resonant antenna or even a 5/8th wave which
>tries (if I understand it) to squish the pattern down from a sphere to a

If you start with a monopole, shortening the antenna in half with a
loading coil will result in half the gain or -3dB loss. 1/4th the
length is 1/4th the gain or -6dB loss. Etc. Shortening the antenna
doesn't change the pattern much. You still end up with roughly a
torus (donut) pattern. The torus is far from perfect and probably
resembles more of a sphere. Therefore, you don't have to worry much
about the loss of signal in the axial directions.

A 5/8 wave antenna is the longest length (and therefore highest gain)
antenna that can be built before the antenna pattern starts to
resemble a cloverleaf (with deep nulls). The gain is about 1.5dB more
than a dipole. That's a fabulous 19% increase, which is kinda
marginal considering the added length.

All this assumes that some effort has been made to match the proposed
antenna to 50 ohms.

>In my mind I would simply like an antenna that was effective but
>flexable.

Flexible as in like rubber? Or flexible as in versatile?

>Length is not "critical" as I plan to hang it up high on an
>LB harness. The idea is a rough and tumble antenna that can work in the
>woods on a Search and Rescue mission but will give me the very best
>range out (not so much up/dn)

Large antennas in the brush is a bad idea. It will tangle with the brush and the brush always wins. Your requirements are probably the same as any emergency responder. It has to be unobtrusive (not get in the way) but still effective. Smashing through the brush with a 5/8 wave 2m antenna is not my idea of unobtrusive.

My suggestion is to have two antennas. One is the traditional 6" rubber ducky antenna that comes with most HT's. It's not great, but it's small enough not to get in the way. In your back pack, carry a length of RG-58/u with the last 19" of braid pulled back over the outer jacket. This forms a "coaxial antenna", where the exposed 19" of center conductor is the driven element, and the folded back braid is the counterpoise. The impedance is officially 70 ohms, but the mismatch loss to 50 ohms is minimal. The trick is that this antenna is attached with a long length of coax cable, that can be thrown into the trees, or hoisted on a pole, to get added elevation.

If you have a harness, it might be possible to sew an antenna into the webbing. While not the best for gain and non-directionality, it is very convenient not to have an antenna sticking you in the armpit.

>Has anyone done any serious work with HT antennas?

Ummm... the cell phone and public safety radio sector has done considerable work on optimizing the antenna. The cell phone horde has decided that non-projecting antennas are more important than convenience. They've also decided that it's acceptable to place the antenna at the BASE of the cell phone (as in the Motorola RAZR). Convenience is more important than performance. The public safety and land mobile sector has correctly decided to solve the problem at the other end of the link. They're leaving the antennas at about 3-6" in length, and concentrating on improving performance by adding sites, better base antennas, voting systems, etc. Why mess with 1,000 HT's when you can get better results by improving one mountaintop site?

There are also external speaker microphones for HT's that have antennas in the microphone (thus insuring that your brain gets the maximum RF exposure).
<http://www.dhgate.com/kmc-26-microphone-speaker-mic-for-kenwood/p-ff808081220be3b101220d87650c1504.html>

>Is there anyone
>clued into how to match these properly?

Sure. The 5/8 wave uses a transformer or tapped inductor to step up the 50 ohms to about 1000 ohms. Shorter than 1/4 wave antennas use a loading coil (series inductor). 70 ohm coax antennas and 35 ohm monopoles are close enough to 50 ohms for VSWR not to be an issue. The added bulk and RF losses of the matching system, has to be balanced against the antenna mismatch loss. It's often better to tolerate the mismatch loss.

>And has anyone looking into
>using spring steel (Such as Measuring tape) for the antenna as the

>Military uses in many of their radios?

<http://theleggios.net/wb2hol/projects/rdf/tape_bm.htm>
<http://www.open-circuit.co.uk/tape.php>
The problem is that spring steel (as found on a tape measure) is not exactly a good RF conductor. The military HF dipole antennas I played with were stainless steel, which has better surface conductivity.
<http://www.qsl.net/n2ckh/HA4000.htm>
The problem with tape measure antennas at VHF and UHF is accuracy. The cut length of the antenna needs to be fairly accurate to work at UHF. For example, the difference in length of a UHF 1/4 wave radiator is:
440 MHz = 170.5 mm
450 MHz = 166.7 mm
To get it somewhere in the band, you need to adjust the tape measure to within plus or minus 1.9mm. That's not easy (or practical). There's also no antenna tuner to compensate for errors. That's why field adjustable antennas are not very popular at UHF frequencies.

Instead of floundering around with generalities, could you kindly disclose what problem you're trying to solve and what equipment you have to work with? Perhaps the answers will be more specific.

>Thanks for any thoughts on this de Jay W0VNE

Hint: Making a better HT antenna is easy. Making one that is better but also smaller, more efficient, and ergonomic, is not so easy.

Hello James,

As you know, every mA that goes into the antenna, has to come from the shield from the coaxial cable, or the jack on your HT. From there, the current is pulled out of your hand (assuming VHF). Your had acts as the counterpoise.

The lower the radiation resistance, the more current goes into the antenna given same power. To reduce the current, and losses, in your hand, a half wave resonating antenna is my preferred option. The only "problem" with the HW antenna is that you need a descent match because of that high radiation resistance (several hundreds to kOhms depending on length/thickness ratio).

As others said, the sleeve dipole is an attractive option when you can erect it into a tree. Because of the plastic sheet that is between the shield and the folded back shield, the length must be less then a quarter wave to have good choking function. To get the antenna in resonance, the "radiator" section has to be bit longer. Note that the folded back braid does radiate as much as the upper part.

The 5/8 lambda antenna only has its gain advantage when the image antenna is present. As there is no image (as you don't have an infinite ground plane), the HW antenna will perform better then the 5/8 lambda antenna.

I support Jeff's strategy, have a small easy to handle one for normal use, and the good very flexible one for when it is really necessary.

Thanks. I'm at home with a cold, flu, or allergy and am stuffed full
of pharmaceuticals. This tends to stimulate my imagination and
creativity. Any tendencies towards insanity is strictly chemically
induced.

Many years ago (1970's), I was into back packing, camping, and
trespassing on government property. In order to be fully prepared, I
had my VHF HT (Motorola HT 200, HT220 or worse) and a selection of
antennas. For local communications (warning if the authorities are
coming), the HT's would usually have the stock Motorola rubber ducky
antenna. However, I wanted to carry something with more gain for long
range communications. It had to be small, light, portable, foldable,
cheap, and have lots of gain. The result was a rope yagi.
<http://www.bigskyspaces.com/w7gj/longyagi.htm>
<http://www.racine.ra.it/ariravenna/EME%20BIF/IW4BIF_eng.htm>
(etc...)
I have photos of mine somewhere, but the above are better built. Mine
was only about 20ft long. The elements were #14 AWG bare copper
electrical ground wire. The rope was white nylon braid. The driven
element was 1/4" aluminum tubing with a T-match. Usable bandwidth was
horrible with something like 200KHz for <2:1 at 146 MHz.

Roll forward a few years and decided that inflatables were the next
big thing. Instead of a mess of rope and wire, I would carry a pair
of vinyl tubes supporting the yagi elements. The vinyl tube of choice
was a roll of polyethylene tubing:
<http://www.uline.com/BL_2105/Black-Heavy-Duty-Poly-Tubing>
This was inflated with an air mattress electric or foot pump. Tubular
sleeves were glued to the poly boom for the elements. Otherwise, it's
similar to the rope and wire yagi, but smaller and lighter.

After a few more years, my sanity failed to re-appear. I was looking
at a friends service van and noticed that the ladder looked like a
suitable candidate for a yagi. Fiberglass (insulating) frame with
aluminum rungs. A bit of modeling and some measurements with a
network analyzer showed that the ladder might work. The rungs were
22" long, which is a bit long for 146MHz. Some series capacitance and
a gamma match got it to tune. Note that a Yagi antenna does NOT need
to be a dipole, and will work as a monopole if you can tolerate having
the gain peak off center. No photos because I never got beyond the

tinkering stage. Still, for emergency use, borrowing one of the
served agencies ladders for an antenna might prove entertaining.

More recently, I got back to the inflatable idea. Instead of an
inflatable antenna, I decided the world needed an inflatable tower or
mast. The idea is that the higher the VHF antenna, the better it
works. Never mind gain. It's not really a new idea as the military
has been using it for a time:
<http://towers.ltaprojects.com/LTA_Towers/LTA_Tower_Home.html>
Note the ham and CERT versions. The videos are worth watching.
<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=250617992381>
$1200 for the 25 ft version. Ouch.

Using the same poly tubing, I constructed a 20 ft unguyed vertical
mast, which promptly buckled and blew over in the slightest breeze.
Adding guy wires at the top helped, but the slightest buckling, would
precipitate a collapse. To prevent buckling, I increased the air
pressure until I blew out the side. 50 PSI max for 4 mil tubing.
Adding more guy wires will work, but now it's becoming complexicated.
Instead, I added four radial arms of smaller tubing as a base and tied
the multiple guy ropes to the ends. The inflation pressure provided
the necessary tension. That worked.

[Begin math warning] The load that can be carried by a vertical
column of air (in a poly tube) is equal to the air pressure times the
area of the cylinder. The tubing is sold by the flat width, which is
half the circumference. Therefore, a 6" tube has a circumference of
12". The radius would be:
r = C/(2*Pi) = 12 / (2*3.14) = 1.9 inches radius
The cross sectional area is therefore:
A = Pi * r^2 = 3.14 * 1.9^2 = 11.5 sq in
If I inflate the tube to 10 PSI, the maximum load is:
MaxLoad = 11.5 sq-in * 10 lbs/sq-in = 115 lbs
Unfortunately, with 115 lbs of antenna at the top, there no safety
factor. My guess(tm) is about 5:1 would be about right, thus limiting
the max load for this derangement to about 24 lbs (including the coax
cable).
[End math]

What this means is that you're not going to drag this monster on Field
Day and use it to raise an HF beam, rotate, and heavy coax cable.
However, it might handle a simple VHF omni and thin coax.

This isn't at all true generally. Shortening an antenna doesn't by itself reduce the gain significantly -- less than 1/2 dB going from a half wavelength dipole to an infinitesimally short one, due to change in current distribution. Shorter antennas are typically less efficient than longer ones due to loss in the matching components, whether those components are in the form of a loading coil or some external matching network, and ground loss if significant current flows through the ground. And the amount of loss varies a great deal depending on the components and other factors. Because of this, no firm number can be attached to the change in efficiency or field strength with length, and even approximate numbers should be viewed with suspicion.

The gain of a 5/8 wavelength radiator over a quarter wavelength under ideal conditions is about 2.8 dB, not 1.5. The pattern is already beginning to resemble a cloverleaf at this length, with a high-angle lobe. But the high lobes aren't yet quite big enough to significantly reduce the power in the main lobe, resulting in the gain. But this is under ideal conditions, with perfect ground reflection. In an HT environment, all bets are off. I personally use a half wavelength whip on an HT, because its high end impedance minimizes current to the HT and my body, leaving the whip itself to do most of the radiating.

Antennas are a lot easier to understand if you forget about "ground"
unless you're talking about a direct connection to the earth. Calling
one side of an antenna "ground" doesn't impart special qualities;
current flowing on any conductor creates a field, and it doesn't matter
if it's on a "ground" side of an antenna or any other part of it. Some
structures like a "ground plane" elevated radial system are designed to
carry current yet radiate very little, so they're reasonably called
"counterpoises".

A rubber ducky has, for practical purposes, exactly the same pattern as
a quarter wavelength antenna. Longer antennas have different patterns.
But remember, your HT and body are just as much a part of the radiating
antenna system as the "antenna". If you put, say, a half wave whip onto
your HT, your body and HT are more effectively removed from the system
(although they'll still radiate some due to coupled current). That will
likely make more of a difference to the pattern than the difference
caused by whip length.

I'd think military implementations deserve a good look, since they have
similar requirements to yours. Any solution will be a trade-off, so you
have to decide what you're willing to trade for what you'll get.

I recommend you get the _ARRL Antenna Compendium, Vol. 4_ and read "An Investigation of 2-Meter HT Antenna Performance" by Ken Pierpoint KF0OW and Ed Brummer W4RTZ. It's the only experimental work I know of on the topic which has been published in the civilian press. The results aren't totally unambiguous, but it's a good study.

There are others on the group who can get into the technical side of things -- I just thought I'd tell you what I'd use in the bush, or anywhere else for that matter. Make up a twin lead J-pole -- its flexible and you can hang it from almost anything. If you Google J-pole you'll find a hundred different designs, but electrically they are all the same thing. The twin-lead version can be hung anywhere from a string, and then rolls up and fits in your pocket when you're done. If you want you can hang it on a stick or twig tied to your backpack! A very easy to make, versatile, and effective antenna! It's the only one you'll ever really need!

I tried that a long time ago and came to a different conclusion. What I found in the remote areas was a lot of multipath reception. Sorry about the technical term -- the consequence of multipath is that the signal strength changes dramatically as you move. It's the cause of the "picket fencing" familiar to mobile operators. Changing antenna position even a few inches can take a signal from unreadable to nearly full quieting. With an HT mounted whip, I move the HT around until I hit a hot spot, and hold it there while communicating. When I hung an antenna from a tree, it was a crap shoot (how's that for keeping it non-technical?) whether it would end up at a hot spot or a lousy spot.

Sorry, I missed the suggestion of hanging the J-pole from your backpack. That would allow moving around for the best reception in the multipath environment. My comments were in response to the suggestion of hanging it from a string, which I found not to be a good idea.

Like most vertical radiators isolated from earth ground, a J-pole can couple quite a bit of current to the feedline, making the feedline, rig, and your body part of the antenna system. So you might find some feedline lengths and orientations to work better than others.

> What better place exists to delve further into the Masters thoughts
> rather than the manufacture of another theorem?

To justify another theorem you must do a couple things:
1. predict something that is not currently predicted.
2. explain all known phenomenon at least as well as existing laws/
theories.

In order to do both of those you must be quantitative. Provide exact
equations that combine what is predicted by maxwell with your magical
levitating colored bosons from the sun, show the link to the earth
rotation precisely so the tipping effect can be calculated and proven
or disproved by an experiment, explain why diamagnetic materials must
be used and what happens differently if you use paramagnetic or
ferromagnetic materials in a form that can be measured... but these
all require equations, not handwaving general statements about the big
bang and your magical equilibrium.

wrongo buckaroo. there is no such thing as a monopole... when you have a feedline are there not always 2 conductors? search for some basic circuit theory about current and voltage sources, you will see they always have 2 ports. there must always be a return path that is the other half of the dipole, even if you can't see it as such. all antennas derive from the infinitesimal dipole which when degenerated even father can be represented as a single oscillating charge. it always goes back and forth or around in circles to create the propagating wave, if it only moves in one direction as it would have to in a monopole there is no wave only a simple field.

have you ever measured the charge on an electron? that is a standard
college physics lab experiment, measure charge and mass and compare to
text book values. a very simple experiment actually, look up the
millikan oil drop experiment and give it a try. maybe you could get
together with art and go through a few of those simple experiments to
gain a better understanding of basic physics.

they may have the same patterns for some cases, that is why they are
used in lower grades, to keep the explanations of waves simple for
those who don't have the mathematical background to understand the
full detail of it. but pattern does not show polarization. by
matching an interference pattern you are not showing how a wave is
polarized, only that superposition principles work for both types of
waves. show me an experiment where a sound wave is polarized, that
one i would like to see. you might want to start with a couple of
these:

<With an HT, the radio and the person holding it are the lower half
<of the antenna if using a 1/4 wave or 5/8 wave. And yes, a full
<length antenna will trounce most rubber ducks.
<A good antenna for HT's is the half wave. But I've seen the 5/8's
<do pretty well even considering the problems.
<A 1/4 wave is a good cheap antenna. IE: get an adapter that
<converts the rubber duck connector to a SO-239. Then stick
<a 1/4 wave whip in the center pin hole. Quicky 1/4 wave that will eat
<most all rubber ducks. And using external ground planes, verticals
<works well too.
-
At one time, I did troubleshooting on a manpack radio (that dates the event)
that had a battery operated data terminal connected to the radio. Pressing
the transmit button would terminate the data. The problem was that the
cable length from the radio to the data terminal was almost exactly 1/4
resonant. The radio loved the arrangement....the data terminal didn't like
the voltage.

1434. DX, RF radiation efficiency, and Orgonite

Newsgroup: rec.radio.amateur.antenna
Date: 2010-05-08 16:36:14 UTC
From: Jeff Liebermann <jeffl@cruzio.com>
Message-ID: <3a3bu51ptcpctgj0j7lbraus9r6m1n5qme@4ax.com>
Source record: 10034

It has come to my attention that my inability to effectively work DX stations might not be due to my baling wire antenna, Romex feed line, broken HF radios, or obnoxious operating style. It's quite possible that someone buried some Orgonite near my QTH, which is interfering by converting my negative energy (RF) into positive energy (good weather, positive attitude, good karma, etc).

<http://www.orgonite.info>
We have found that tactical deployment of Orgonite
(e.g., "gifting") by throwing, hiding or burying it near
sources of electromagnetic radiation or other pollution
or in polluted areas, such as near cellphone/TV/radio
towers, power plants, in lakes, rivers and ocean harbors,
has a powerful and noticeable effect on the area. The skies
get clearer and return to the deep blue color you remember
from your childhood, complete with normal puffy white clouds.
(etc...)

Orgonite stones are apparently made by encapsulating quartz crystals or amorphous quartz in casting resin, resulting the required RF neutralizing strange shapes. While I have yet to find any Orgonite in the yard, the digging and exercise seems to have produced some positive energy. Anyway, if you notice that your equipment or location is not working as expected, search for Orgonite crystals like these:
<http://www.google.com/images?q=orgonite>
<http://www.orgonecrystals.com>

Source record: 10035

I need a one to one un-un to isolate common mode currents on a feed line that is fitted with N connectors. The power level is 100 Watts or less. Just for the sake of having some margin a two hundred watt design would be good.

Hi Owen

I mean "any matching property" in the sense that we give to a coupling
condenser in electronic circuits.

Another possibility could be that it was a method to trim the resonant
frequency easily from the center of the structure without to cut the
tube neither to make it telescopic making the element a little more
longer. I don`t know, I hoped to obtain a correct answer looking for
it in the Web.

At worse, maybe that system never existed. I only remember sometimes
heard speak about it in the eter or a mailing list :>)

Thank you very much for your helping

Another speculation...

Increasing dipole length radiation resistance increases. Could be a
method devised to take advantage of that effect using the condenser to
take the antenna to resonance again

Will it compensate the increase in the radiation resistance the higher losses in coaxial condenser?

Miguel

>wrongo buckaroo. there is no such thing as a monopole... when you
have a feedline are there not always 2 conductors? search for some

basic circuit theory about current and voltage sources, you will see
they always have 2 ports. there must always be a return path that is
the other half of the dipole, even if you can't see it as such. all
antennas derive from the infinitesimal dipole which when degenerated
even father can be represented as a single oscillating charge. it
always goes back and forth or around in circles to create the
propagating wave,

Yes. But one end of the dipole may have the better conditions to propagate.

>if it only moves in one direction as it would have
to in a monopole there is no wave only a simple field.

I am writing about a dipole with one end visible and the second shielded.

In nature is always as you wrote. The both ands are always "visible".

Light is always directional. Radio waves can be omnidirectional.
Of course light is emitted by many dipoles. Radio waves by halve, one, two
(circular polarity) or many (phase radar).

You assume that radio wave is transversal. Such are polarised. But such are
only in Maxwell's Hypothesis.

Radio waves from the ends of the dipole are coupled. The both are in one
plane.

Radio wave from one end is spherical.

>only that superposition principles work for both types of

>have you ever measured the charge on an electron? that is a standard
college physics lab experiment, measure charge and mass and compare to
text book values. a very simple experiment actually, look up the
millikan oil drop experiment and give it a try. maybe you could get
together with art and go through a few of those simple experiments to
gain a better understanding of basic physics.

Almost all Authors of tekstbooks write that it was a big mistake of Maxwell
when he assumed that electricity is massles and incompressible. They wrote
it after discovery of electron.

Now we assume that the electron gas is the electricity.
What do you think. Is the electron a charged particle or pure electricity?

How does one accelerate a charge, field or
wave?
Does it distort in any way when you push it?
What do you use to push it?
Does a receiver catch it without distorting it?
Can you put the charge,field or wave into a speaker to listen to at a
later time?
Can you re arrange them and send them back at a later time?
How many charges make up a wave?
How many waves fit into a field?
Can a field of waves support an oil slick?

In textbooks must be all theories.
In one chapter light (and radio waves) is like photons, in the next chapter
like EM waves and in next like acoustics.

EM is the only example of transversal waves. So it must be in teaching
program.

But we try to help Peter. He wrote: "I begin to appreciate a comment made by
a fellow radio amateur and
technician that antenna theory was 15% science and 85% black magic! "

It seems that you are sure that radio waves are transversal. It is
impossible to help you (Maxwell was full of doubts).
May be that somebody consider the Acoustic analogy and the black magic
disappear for him.

Light is not coherent. So dipole radiate for very short time.
Radio waves are coherent and can be from one source. It is easy to analyse
them.
Are they transversal?

maxwell may have been full of doubts, and Einstein wasn't able to see
the experiments that have proven his theories, but we have seen them
well tested and accepted over the years. if you think that 85% is
black magic then you have lots of learning to do to fill in that 85%
gap in your knowledge.

> How does one accelerate a charge, field or
> wave?

a charged particle can be accelerated in many ways. an
electromagnetic field or wave can not be accelerated, it travels at c
in the medium it is in no matter what you do to it.

> Does it distort in any way when you push it?
> What do you use to push it?

can you measure the distortion of a particle? that would be
interesting to see. as above, you can't push a field or wave.

> Does a receiver catch it without distorting it?

only if you don't exceed it's dynamic range.

> Can you put the charge,field or wave into a speaker to listen to at a
> later time?

only if you don't violate it's copyright.

> Can you re arrange them and send them back at a later time?

sure, that is what mirrors do. the image that you see of yourself is
delayed by the time it takes light to travel from your fact to it and
back, and is then reversed in the process.

> How many charges make up a wave?

none.

> How many waves fit into a field?

none, fields make up waves... much like those amber waves of grain in
the field.

> Can a field of waves support an oil slick?

no, but an ocean wave can swamp a field hand.

1452. Variable Geometry Antenna

I have been thinking about the SteppIR Antennas. There is no way I will ever justify the money for one. Has anyone pondered the problems from a HomeBrew stand point. It seems to me that the first challenge is to couple the radiator to the feed line. The rest is simply (maybe simply is not the right word...) mechanics.

Whatever form the radiator takes it needs to be wound on a spool like mechanism.

Google does show some hits...

Maxwell did EM, Einstein did the photons and somebody else the acoustic
analogy.

>but we have seen them
well tested and accepted over the years.

All of that three (all three are in textbooks) are well tested and accepted
but only in some extend. May be that after some time only one will be fully
accepted. Which one do you designate?

> if you think that 85% is
black magic then you have lots of learning to do to fill in that 85% gap in
your knowledge.

I designate the acoustic analogy and do not see any gaps.
They who designate EM or the photons are in constant trouble for more than
100 years.

"The most monochromatic sources are usually lasers; such high
monochromaticity implies long coherence lengths (up to hundreds of meters).
For example, a stabilized helium-neon laser can produce light with coherence
lengths in excess of 5 m. Not all lasers are monochromatic, however (e.g.
for a mode-locked Ti-sapphire laser, ?? ? 2 nm - 70 nm). LEDs are
characterized by ?? ? 50 nm, and tungsten filament lights exhibit ?? ? 600
nm, so these sources have shorter coherence times than the most
monochromatic lasers". From:

http://en.wikipedia.org/wiki/Coherence_(physics)

Up to now light is not coherent. But in future who knows.

Well, if you're going to clone it, these might offer some clues:
<www.w4gkf.com/steppir/>
Lots of photos. Perforated flat copper "tape" is used for the
elements. Sprokets inside the motor assembly unroll the tape from a
spool which is then fed into the fiberglass support tubes. The
electrical connections to the elements is with a simple wiper contact.
There's a view of the guts about 4 photos down from the top:
<http://www.w4gkf.com/steppir/n4dk/>

Some interesting stuff from the patent:
<http://www.google.com/patents/about?id=CjKhAAAAEBAJ&dq=steppir>

If you're planning on cloning the antenna, I suspect your biggest
challenge will be the wide variety of custom fabricated mechanical
parts required. Making adjustments and modifications on top of a
tower is also not my idea of fun. I could probably design one
suitable for home brew, using round wires on spools with pulleys at
the element ends, but the result will probably not survive the first
storm.

you may designate away, that doesn't make it any more correct. the
only things that the acoustic, water, and em radiation has in common
is the sinusoidal characteristics and that superposition works.
because of those two you can get similar interference patterns from
all 3 types of waves. that doesn't mean the underlying physics are
the same.

if you are going to be that critical then its hard to call radio waves
coherent either. every transmitter has some drift, phase noise, or
harmonic content that distorts the pure sine waveform one way or
another making them incoherent in longer periods, the same way there
is noise and incoherence in lasers... nothing is perfect.

Jim wrote: " Having some similar charactristics does not mean EM and sound
are the
same thing."

They are not the same. Sound propagate in gases, liquids and solids
Electric waves in the "aether".

But the source of sound is an increase of the pressure.
The source of electric waves is an increase of the voltage.

The voltage increases at the ends of a dipole.

The electric waves and sound propagate in metal wires, but with different
speeds.
Are electric waves in a wire also transversal?

because of those two you can get similar interference patterns from
all 3 types of waves. that doesn't mean the underlying physics are
the same.

Oscillating compressible gas create .the standing waves in the tube with the
closed end.
The oscillating compressible electron gas create the standing waves in open
circuit (antenna).
Is not the same physics?

This is a looooooong way away from the Orgone that Orson Bean went
gaga over on TV (something that somehow skirted censoring):
http://www.educationrevolution.org/orgone.html

I forget where I saw him make his pitch - must have been to a
thunderstruck Johnny Carson.

To cut to the chase, Orson made claims of something absolutely
miraculous that happened to him in the orgone box:
"The box was a closet-size container made of sheet metal and Celotex.
It was said to gather 'orgone energy' from the cosmos and transmit it,
with beneficial psychological effects, to anyone who sat inside."

1463. Computer model experiment

Newsgroup: rec.radio.amateur.antenna
Date: 2010-05-10 17:35:33 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <06c13009-6fdd-4571-832c-ac467ea582be@l28g2000yqd.googlegroups.com>
Source record: 9963

I just completed a experiment with my antenna optimizer program where
I had a dipole in free space and where I increased the diameter until
it was close to.003 ohms resistive
What this means is the current flow is right at the surface where
there is no skin depth
penetration involved and thus close to zero material resistance. This
means that the total resistance is the radiation resistance of the
surface encapsulating particles. The radiation was 35 db in a shape
close to that of a sphere. (when the resistance of the aluminum dipole
went to zero the radiation went to a perfect sphere) Efficiency was
stated at 100% efficient pointing to 100% accountability for all
forces involved and where losses were at a minimum.
Regards
Art

The radiation was "35 db" compared to what reference value?

BTW, a single, linear radiator cannot generate a perfectly spherical
radiation pattern, no matter what your model tells you.

Even an "infinitesimally" short, center-fed linear dipole has a figure
8 radiation pattern with a directivity (gain) of 1.5 X, or 1.76 dBi
-- see any antenna engineering textbook.

I believe the computer programs to be more up to date than the books!
There certainly have been more advances since they have come into
being.
The programs reflect Maxwells equations which support the presence of
particles which is what provide the radiation resistance and not the
dipole itself. The dipole will show a donut pattern that will
gradually deform to a perfect sphere when resistance drops to zero as
per Poynting.
I would also point out that the programs support the presence of
Gaussian static particles as does mathematics. I would imagine that no
matter what programs you decide to use you will get the same results
as you increase the element diameter until the impedance is zero.No
point in trashing computer programs in advance because of personal
intuition. All I have done is removing resistance losses that do not
contribute to radiation.

Where is Lurch when I need him.... Grrrrrrrrrrrrrrrr...
Once again , delusions of grandeur induced by misuse of antenna
modeling programs. :/

the programs are based on the books... but even worse, they are
digital approximations of the continuous formulas and as such are not
completely accurate. this is especially true when extremely large or
small numbers are used or there are a large number of additions done,
as is common in antenna modeling programs. there are also assumptions
made in the development of most of those programs that are often not

stated to, or not understood by, the user, such as you. so when you set something to optimize forever or start making elements extremely skinny, fat, short, or long, or too close together, you are most likely going to get wrong, or physically unrealizable results.

Thanks for the url's. I am not trying to clone it, just impliment the
concept. I do my antenna work on the ground with a minerature version
of the Tilt-Plate concept. I do my antenna work with both feet firmly
on the ground.

A Home Brew version of the variable geometry beam antenna seems to me
like a good place to learn a bit.

Obviously you are very experienced in generating
and bug catching in antenna programs having large experiences of
finding antenna errors.
What exactly in the nature of antenna computer programs, which have
been around for some time now, have you found them to be suspect ?
In my case the program verified what mathematics show as the presence
of particles on the surface and where the total input forces were used
for particle propagation. Now I am aware you have taken the position
that particles are not involved in radiation and thus you will resist
what computer programs arrive at relying on your intuition at all
times which requires no personal experience on the subject
However, I am taking the program that I purchased on trust especially
when it follows the maxwell equations and where I am not adverse to
change.
I look forward to specific examples that buttress your thoughts in a
scientific manner so I may decide what to do with my program purchase.
May I recommend you do the same thing with the program of your choice
where you can specifically point to the areas of error where they do
not meet your expectations. Why not do the same with EZNEC so Roy can
learn from your personal experiences and intuitions and institute the
appropriate corrections. Never mind the length of the dipole just make
the diameter very very fat and see what EZNEC does.

Groan... Let me tell you the story about 24 dbi gain dipoles...
Simple to model.. Then again, no, it's a futile waste of time trying
to
convince you of the error of your ways.. :/
Continue with fantasy hour... :/

What ever program you use let me know the result for a fat dipole.
Walk the walk ! Forget the talk!

As Clint said in the wonderful old movie, "A man's gotta know his
limits". For antenna modelers it should read, "A man's gotta know the
program's limits".

Of course, Art thinks things have changed and the computer modelers have
a better grasp upon reality than the ones even he calls "the masters".
He is an example of the blind man leading himself.

Great, tho most people on the group have yet to learn about antenna
programs preferring to procede by intuition.
Choose a dipole suitable for a particular frequency
in FREE SPACE.
Increase diameter incrementaly in the order of 1000
inches or so.
Plot radiation field
Continue until impedance drops to much less than 1 ohm (I dropped to
about .003 ohms) Plot radiation pattern and compare change from donut
to sphere shape of pattern and compare results.
What to expect.
Radiation will increase as impedance decreases.
Maximum radiation will occur when the dipole impedance drops to zero
and the particle skin becomes the sole resistance of the composite
dipole.
The radiation pattern will reflect point radiation within the cosmos.
Note some programs provide an impedance in negative terms. It is
better that impedance stays positive to determine all trends.

No Tom, programs are based on Maxwells equations and the stipulation
of equilibrium.
Hams use this same program for yagi design that is NOT in accordance
with Maxwells equation.
Thus programmers modify the contents to suit what the customer wants
so they make money by making the customer happy. It is hams that are
following the one eyed man by living with garbage.
Which is OK as they know no better to strive for.

So the programs are based on Maxwell and your equlibrium, and then you say they are not because of greed. B as in B, S as in S. What are these programs you haven't named?

And what program is the yagi program you won't name?

Will you give anyone on the list one shred of a tiny piece of a fact for once in your life?

We already know the answer. You can't, because it's all fantasy. None of it exists, and therefore you can't point at a single program. It's all there in your twisted mind but exists nowhere else.

The computer program should know its limits. Anytine a program allows the data entered to be too large or small for the calculations, it should be flagged as being out of range. Also many computer programs will use simplified formulars that can mast the true outcome. Usually it is not very much, but as all errors start to add up the end results may be way off.

I often enter data that I know will be difficult for programs to use. If the program gives an answer then I usually don't use that program expecting a exect answer.
Back in the Windows 3.1 and 3.11 days the simple calculator would give wrong answers to simple problems. I think if you entered 3.11 and subtracted 3.1 from it you got the wrong answer. That program was not corrected by Microsoft.

I disagree. The program cannot "know" its limits if the problem it's
modeling is complex enough. So the user must understand the program and
especially the math related to what the program is modeling.

Blaming the program for giving you the "wrong" answer is like blaming
the tires for hitting the guard rail because you exceeded their limits.
Those limits are not the same under varying conditions and must be
filtered by experience and understanding.

Ralph, the computer program I use is AO pro which is equipt with an
optimiser and based on Maxwells equation. It is required to provide
arrays where the whole is in equilibrium as is its parts where all
forces are taken into account according to boundary rules.
It is quite easy to confirm if the results are in equilibrium.There
are many programs that arer similar
only they will not crunch the numbers as an optimiser will but instead
calculate only from your input but without alteration. These also are
based on Maxwells equations. However hams are bound to Yagi style
antenna designs which are planar and not in equilibrium. This style of
program is modified to encompass its primary use. There are also
programs that are specifically designed for planar arrangement only
per the Yagi and are not based solely on Maxwell equations that demand

equilibrium.
To apply any of these programs is ok for a dipole in free space say for 14 Mhz and should give the same results. Same goes if one changes the diameter as will the radiation pattern provided. So in this particular
situation it matters not what program one uses the results will be the same. To conform with Maxwells equation equilibrium is demanded ie all vectors add up to zero.Since it is based on boundary rules one can make a static field dynamic which thus includes particles where the result is applicable to Maxwells equations. Thus we have an conductive element covered or encapsulated by particles the later being dynamic.This produces two resistances, the element and the particle skin. The element resistance goes to zero as the current flow moves towards the surface thus removing skin penetration losses and where all energy input is applied to propagation where we get accountability for all forces resulting in an array or element where all is in equilibrium without being planar as one must account for the earths rotation vector as well as that for gravity otherwise equilibrium cannot be retained. Thus as the diameter of the element is increased so does the surface increase for the resting particles such that the applied energy equals the energy required to elevate and propagate the supplied particles. without penetrating the surface of the element. This way we do not get into the situation of dealing with the sharing of the total resistance and thus removing element losses that do nothing for propagation, at the same time balancing the propagation vectors upon the particles alone to the applied energy.
All basic classical physics which uses only fully accepted rules of the masters without alteration of any kind as predicted by Einstein in his search for the std model.

> The computer program should know its limits.

yes and no. For EM modeling codes originally intended for use by sophisticated users with a knowledge of the limitations of numerical analysis, they might assume the user knows enough to formulate models that are "well conditioned", or how to experiment to determine this. NEC is the leading example here. It doesn't do much checking of the inputs, and assumes you know what you are doing.

There were modeling articles in ARRL pubs 20 years ago that described one way to do this at a simple level: changing the number of segments in the model and seeing if the results change. The "average gain test" is another way.

In many cases, the constraints on the model are not simply representable (a lot of "it depends"), so that raises an issue for a "design rule checker" that is reasonably robust. Some products that use NEC as the backend put a checker on the front (4nec2, for instance, warns you about length/diameter ratios, almost intersections, and the like)

It's sort of like power tools vs hand tools. The assumption is that the user of the power tool knows how to use it.

Anytine a program allows the
> data entered to be too large or small for the calculations, it should be

> much, but as all errors start to add up the end results may be way off.

There's whole books written on this for NEC. Part I of the NEC documents, in particular, discusses this. There's also a huge

professional literature on various FEM computational techniques and
their limitations. NEC, like most numerical codes (for mechanics,
thermal, as well as EM), is very much a chainsaw without safety guards.
It's up to the user to wear gloves and goggles and not cut their leg off.

1490. Feeding System found it => Mosley

Hi

I found it (thank you to all for your helping)

The name of the feeding system I was looking for is:" Balanced
Capacitive Matching", and as Ralph Mowery said, it is a system
patented by the Mosley company see =>
http://www.mosley-electronics.com/page%20files/faq.htm
for explanations.

Mosley people says that its function is the one that I supposed in
third term => to increase the radiation resistance lengthening the
element.

When I search the web for the first time I didn't find it because I
looked for "T33".
My friend Luis Fernández - LU1DMA - mentioned again (in another radio
list) a Mosley "TA-33" and with this new Google key I gave immediately
with her.
LU1DMA tell me that he has a "Mosley TA-33" and a "Palombo" antenna
(local production, the last) and that both use this feeding type =>

http://xa.yimg.com/kq/groups/15085895/213843572/name/adaptador.pdf

that it is not identical to the one that Mosley describes in its FAQ.

Could this be a later variant they add to the lengthening effect of
their original system with the properties that are attributed to the
bazooka system?

Are you sure you have not violated the segment length/wire diameter ratio? From Cebik; Intermediate Antenna Modeling: "In NEC-2 it is especially important to keep the segment length (greater than) about 4 times the wire diameter. You may reduce this value by half by invoking the EK command." Also, what does your "Average Gain Test" report show?

As stated earlier the above is a gross violation of the
segment length/diameter ratio. Again; what does
your "Average Gain Test" report say under these
conditions?

Jim Lux of NASA no less!
All of the programs clearly state that they are based on Maxwells
equations. The bottom line of that equation is that for accountability
for all forces involved are required and where the summation of all
equals zero. This is nothing new and has been followed thru for
centuries. The equations requires first and formost equilibrium and
what the program supplies is easily checked that it meets these
requirements. It is very simple. Showing that the solution is that
inside an arbitrary boundary all within as with the whole must be
resonant and in equilibrium.It requires no more than that to show if
the program has achieved its object. I understand your preachings but
you presented no point that can be discussed.
Now you will respond that I must do such and such to back the
statement above despite that those requirements are the basis of
physics. So to you I will supply the same that I have supplied to
others which they reject, no one has stated why.
A arbitrary gaussian border containing static particles
(not waves as many summize. Gauss was very clear about the presence
of static particles) in equilibrium may be made dynamic by the
addition of a time varying field such that Maxell's equations can be
applied to solve.I have stated the over checks that can be applied to
provide correctness of this procedure. You may, of course, join the
poll that swells on behalf of NASA in opposition to the above but it
would provide me a great deal of delight if you provided more than to
just say "I am wrong". Nobody as yet provided one mathematical reason
that disputes the above, so in the absence of such you will not be
alone, only your credibility suffers but you will remain in the
majority of the poll in the eyes of the ham radio World.

<snip>
I understand your preachings but
> you presented no point that can be discussed.

While NEC and its ilk are clearly based on Maxwell's equations, one should realize that they do not provide an analytical closed form solution, but, rather, are numerical approximations, and are subject to all the limitations inherent in that. They solve for the currents by the method of moments, which is but one way to find a solution, and one that happens to work quite well with things made of wires.

Within the limits of computational precision, for simple cases, where analytical solutions are known to exist, the results of NEC and the analytical solution are identical. That's what validation of the code is all about.

Further, where there is no analytical solution available, measured data on an actual antenna matches that predicted by the model, within experimental uncertainty.

In both of the above situations, the validation has been done many times, by many people, other than the original authors of the software, so NEC fits in the category of "high quality validated modeling tools".

This does not mean, however, that just because NEC is based on Maxwell's equations that you can take anything that is solvable with Maxwell and it will be equally solvable in NEC.

I suspect that one could take the NEC algorithms, and implement a modeling code for, say, a dipole, using an arbitrary precision math

package and get results that are accurate to any desired degree. This would be a lot of work.

It's unclear that this would be useful, except perhaps as an extraordinary proof for an extraordinary claim (e.g. a magic antenna that "can't be modeled in NEC"). However, once you've done all that software development, you'd need independent verification that you correctly implemented it.

This is where a lot of the newer modeling codes come from (e.g. FDTD): they are designed to model things that a method of moments code can't do effectively.

for explanations.

Mosley people says that its function is the one that I supposed in
third term => to increase the radiation resistance lengthening the
element.

The Mosley explanation does not convince me.

Making the radiator somewhat longer than the resonant length can certainly give
birth to a significant series inductive reactance (+j50 ohm in their example),
but can only cause a very modest increase in resistance, certainly not from 30
ohm up to 50 ohm as they state. Probably a resistance value in the range of 32
ohm or so would be realistic.

Nevertheless, applying the series --> parallel impedance transformation, the
impedance of the lengthened antenna (which could be about 32 + j50 as said
before) can be seen as a 50 ohm resistance with an inductive reactance in
PARALLEL, not in SERIES.

The residual reactance could then only be cancelled out using a PARALLEL
capacitor, not a SERIES one.

Could it be that the parallel bar that holds the two halves of the
driven element serves as the parallel capacitor.

It's also possible that the Z goes somewhat higher in resistance, but as
you say, 50 ohms is pretty high. A lot of Yagi designs have feedpoint
impedances in the 10-20 ohm range.

Again you preach but obviously you are not qualified to address the
issue.
Maxwells equations are such that all forces are accounted for when the
array is in a state of equilibrium. To use such an equation for an
array that is not in equilibrium requires additional input
(proximetry equations) which is where error creep in.When an array is
in equilibrium then Maxwell's equations are exact. The proof of the
pudding is that the resulting array is in equilibrium as is its parts.
AO pro by Beasley consistently produces an array in equilibrium when
the optimizer is used as well as including the presence of particles
dictated by Gauss., The program is of Minninec foundation which
obviously does not require the patch work aproach that NEC has. On top
of all that. it sees an element as one in encapsulation as forseen by
Gauss by removing the resistance of the element, which produces a
loss, and thus allows dealing only with all vectors as they deal with
propagation. It is only because hams use Maxwell's equation for
occasions that equilibrium does not exist, such as the yagi, do errors
start to creep in. Any array produced solely by the use of Maxwell's
equations provides proof of association by producing an array in
equilibrium which can be seen as an over check.Like you, I speak only
as an engineer on behalf of myself. Clearly, Maxwell had taken
advantage of the presence of particles when he added displacement
current so that the principle of equilibrium would be adhered to. This
being exactly the same that Faraday did when explaining the
transference from a particle to a time varying current when describing
the workings of the cage.

Hi Tony and Jim

I think that it was not a crazy thing :>) A rapid simulation of a full size three element 20 m Yagi in 4NEC2 software gives me aprox. 32 + j0 ohm with a length of 5.12 m per excited element leg, lengthen to 5,37 m, impedance raises to 37,4 + j51,5 ohm, it is not so much as 50 vs 30 ohm for 50 ohm inductive reactance augment claimed for Mosley guys but if we add some possible losses perhaps that approach was valid enough for them (I should verify more carefully a more real model with loading coils, etc)
Jim idea about paralell capacity it is interesting to think of.

Any way... I wanted discover what was the supporting idea behind that feeding system for its designers and now I got it :>)

Thank you.

As given, the average gain is about 16.7 dB - so one knows that
something-is-afoot . . .
The driven element (wire 1) is essentially touching wire 4. Current in wire
4 is unbelievably high. With use of #30 wire things improve, but wires are
too close.

Thanks for the example. Will use it when next talking about NEC as an
example of what not to do.

maxwell's equations are ALWAYS exact, it is digital models that are
inexact and have limitations due to the approximations made and the
numeric representations used.

Interestingly, MININEC uses the very same method of moments that NEC does, but, because it's "mini" it has substantial limitations. It was developed to fit in small microcomputers of the day. I'd hardly call NEC "patchwork". The two programs do use different formulations for the basis function defining the current on the segment.

There are several papers out there that compare the mechanism of MININEC vs NEC. One might start with the report by Burke and Poggio (for NEC) and the report by Julian, Logam, and Rockway (which talks about MININEC). John Rockway published a paper in 1995 describing the history and differences.

Hi Tony and Jim

I think that it was not a crazy thing :>) A rapid simulation of a full size three element 20 m Yagi in 4NEC2 software gives me aprox. 32 + j0 ohm with a length of 5.12 m per excited element leg, lengthen to 5,37 m, impedance raises to 37,4 + j51,5 ohm, it is not so much as 50 vs 30 ohm for 50 ohm inductive reactance augment claimed for Mosley guys but if we add some possible losses perhaps that approach was valid enough for them (I should verify more carefully a more real model with loading coils, etc)

I tried the EZ-NEC file representing a 50-MHz three-element NBS Yagi.

At resonance (49.95 MHz) impedance is 12.05 + j0

Lengthening the radiating element by about three inches causes impedance to become 14.34 + j50

To show 50-ohm resistance, the antenna losses should cause the birth of a (50-14.34) = 35.66 series resistance. This would cause a loss of about 5.4 dB, so nearly offsetting the antenna gain.

I personaly am extremely happy with AO since I am able always to do an
overcheck with respect
the element resonance. I wouldn't be surprised if the next generation
moved away from the present
algerithms and rely purely on number crunching to obtain systems in
equilibrium. I personaly believe
that the programs would be much more accurate if they had a better
understanding of close elements because of proximetry effects. But as
long as the industry strays away from non planar forms we will have to
live with close approximations. Tho using Maxwell to its limits I have
yet to find a way to concentrate radiation for gain as opposed to
efficiency by the introduction of other elements but I enjoy trying
different methods and there is always a new vista that appears with
its use. My next aproach will be a multiplicity of cells or boundaries
dependent on how far my program can spread. One thing I am absolutely

sure now is that particles are the staple of propagation where the neutrino act as the carrier and can well be the singular particle that Einstein envisaged based on the Earths two vectors.I was absolutely over joyed when AO allowed the radiating elements to gyrate towards zero resistance so that the encapsulating cylinder could be divorced from element thus removing losses. I see no better proof of my aproach in making Gaussian static fields dynamic
which clearly exposes the presence of encapsulation that is substantiated by the math and allows propagation to be viewed as a point source. Next time one visits the moon they can apply a time varying current to the space suit to prevent the carrage of particles to the inside of the ship.

On this I have total agreement. The moment one strays from the concept
of equilibrium is when we expose ourselves to errors.

24 % increment in 20 m example, 19 % in 6 m example. OK, Similar
numbers...

But don't forget that feedeing point impedance not always is near 10
ohms, Yagi feedeing point impedance typically takes values from 40 to
10 ohms depending on spacing, element length, coil loading, etc.

I think: If your assumed numbers were those of the Mosley beam, its SWR would be 4:1(without losses), and with losses included she would be ¡a very nasty antenna!. I think the ham buyers would not be very happy with such a poor antenna on both cases :>)

> K0TAR

I've found it in my best interest to check the consistency of results
in various ways, whenever I can. Often there's more than one way to
think about a problem, and if the answers I get differ, I want to know
why. Until I can resolve the differences, I distrust both (or all...)
answers. I also like to have an idea about the tolerance on the
answers, and many programs (and formulas you use to calculate answers
for yourself) don't give much of a clue about the tolerance. Some are
"exact," and some should be considered only approximations, but often
they don't bother to tell you which. One example is formulas for
calculating the impedance of TEM transmission lines; it's common to
see, for air-dielectric two-wire line, Z0=276*log10(2D/d), but this is

an approximation whose error becomes significant as d approaches D. Even the better formula, Z0=120invcosh(D/d), is not exact: the 120 isn't exactly correct, there's no consideration of finite conductor resistance (and resulting skin depth), and there's no consideration of the atmospheric pressure and relative humidity...

I mostly agree with Tom: don't expect the program, or formula, to know how you are going to misapply it. Try to be aware of what the answers you get imply. Learn the limits of your tools (programs; formulas), and apply them wisely so they will serve you well.

Do I get stung by my own foolishness in not paying proper attention to things like this? You bet I do! Just last night, I entered a coil into the Hamwaves inductance calculator and it was happy to give me an answer. The coil? Ten turns of 1mm wire in a coil 10mm diameter and 10mm long... Duh, that's a 1mm winding pitch and the turns will short together. I didn't think to check that at first. The calculator complains and won't give you an answer if the pitch is less than the wire diameter, but not if it's just equal. Considering the same very useful inductance calculator, I've learned to ignore the answer for the effective shunt stray capacitance: it in general doesn't come close to matching the value calculated from the self-resonance and the inductance. To see what I mean, try entering D=10mm, N=10, len.=20mm, d=1mm, and check what C(L,p) is reported. Now try changing D in 1mm increments up and down. OK, so I don't trust the reported C(L,p) value, but because I've checked several cases of all the other reported values against measurements of actual coils and against one or two other programs I use, I've learned to trust those other reported values, within some tolerance (that's a lot looser than the reported precision in the calculator!). -- I don't mean to pick on that inductance calculator, just to use it to illustrate what applies to pretty much all calculation programs and formulas.

Cheers,
Tom

OK, it also helps to RTFM. The text down below the inductance calculator explains about this some. Also, I should have said that you need to set the "design frequency" to something low (e.g. 10MHz) to see the effect. However, the text suggests that C(L,p) value would be larger than expected...and I've also seen it for some coils to be considerably smaller. So I end up, then, not finding the lumped model including C(L,p) being very useful for the things I do, where I want a model that gives me _decent_ agreement over a broader frequency range, rather than perhaps more exact agreement over a very limited frequency range (as happens when the reported value of C(L,p) gets very large; try "design frequency" = 1MHz for that coil).

Cheers,
Tom

Remember, I have always specified that one does not go beyond the
units supplied by Maxwell, Maxwell did not use lumped loads. It is
stipulated
that equilibrium is paramount as soon as you see the "=" sign. Thus I
can say I am persueing exactnes or accuracy and not fudging.It was
when Maxwell followed the edict of the "equal" sign that he was forced
to add the particle elevation vector by the addition of displacement
current even tho
he could not describe the addition. To him it was a mathematical
equation and nothing else and without explanation of the process.

ok, so you DO agree that maxwell's equations that make no mention of
particles like neutrinos, gravity, coriolis forces, or levitation ARE
correct! And therefor you must agree that the representation of
gauss's law encapsulated in maxwell's equations, WITHOUT an explicit t
in it must be correct! You must also be admitting that your
optimization experiments are full of errors. wow, now its time to go
and rejoice, art has finally come around to the real world!

Again I state. If you are using Maxwell equations you cannot stray
from the units supplied.Hams do not follow the rules with respect
to antennas so approximations are literally garranteed.
Using Maxwells equations alone you have the presence of point
radiation. With a single point radiation the rules of physics state
that radiation limits is in the form of a sphere. If one states you
cannot have a sphere of radiation they are breaking all the laws of
physics and I certainly had no part in the making of the rules.

you can have a spherically symetric static electric field as is easily shown by gauss's law. but in order to have 'radiation' (implying em wave propagating through space) you must have movement of some kind, that immediately removes the spherical symetry by creating an axis defined by the direction of movement. this is why even the theoretical infinitesimal dipole still produces a doughnut shaped field in free space.

Maybe this is good.. I have noticed my antennas tend to actually
work as radiators of RF, where as most of yours seem to prefer
to turn it to heat. :/ I think Maxwell must be taking you for a big
ride. I bet he's up there is the land of the big RF just laughing his
head off at all this silly jibber jabber you keep blaming him for.

How many cases of a single point of radiation have you seen
in the real world, using real world antennas? This is not a trick
question.

Miguel,

I browsed your reference.

The text following "MOSLEY TRAP MASTER AND POWER MASTER SERIES... A Discussion of Beam Antenna Feed Systems" is typical BS that comes from antenna manufacturers with more interest in taking your money than an understanding of how things work.

For example, the justification of unbalanced feed of the split dipole is sheer technical nonsense.

but as dilbert's trolls know, numbers create reality, not the other
way around. if you can't describe it in a formula, it can't exist.
and yes, while the current moves longitudinally along the wire, the
fields are transverse. look at the formulas, they apply to the wire
also. they just get more complex because you have to take into
account the boundry conditions at the interface between the wire and
what is around it... something that freshman physics and calculus are
not enough to handle.

I read on their web page for some more BS.

In explaining why their traps are lossless:

"Gain is a function of element spacing and boom length and not what constitutes an element. The published gain figures for our products are dBd, actual measured gain. Antennas which use other forms of trapping such as linear loading, poor trap copies, baluns or matching devices have inherit loss. "

So, all these things have inherent loss, but not their traps.

Fact is that GAIN is reduced by LOSS, anywhere and everywhere in the system, dB for dB. This includes conductor losses, dielectric losses, and trap losses which they exclude from their definition.

As I said: "I wanted to discover what was the supporting idea behind
that
feeding system for its designers"

Defend commercial stuff and his claims It is not my job (I do not
trust enough in all of them), I am an Amateur :>) but seems to me that
their concept it is not opposed to my modest theoretical knowledge
neither my simulations exercises in 4NEC2 (their "numbers" partially
agree with mine, although I have not simulated exactly a Mosley
antenna model).
Now I am only interested in validate or negate the especific technical
concept and explanation given, from a scientific perspective.

Proposition =>. Is it possible match the impedance of some Yagi
antennas lengthening the driven element and canceling its inductive
reactance splitting the element and adding series caps?
Can be made these caps with special pieces of insulated wire
introduced in element tube?.

Try it... lenghten in a NEC simulation the driven element and cancel
inductive reactance => impedance raises and gain stays (I used
"3YAGI20.NEC" from 4NEC2 examples provided with Arie soft, for
testing).
In my test, raisen length from 5.12 m to 5.85 m per leg, Zin raises
from 31.8 + j2 ohm to 50.9 + j150 ohm and gain stays in 12 dBi (with a
fast ground and 15 m height).

That's a very clever qualitative explanation of, for, instance, why isotropic antennas cannot exist. (without resorting to things like the Hairy Ball Theorem, which is great for explaining polarization)

Ok, since you are discussing impedance matching, what was the effect on
VSWR bandwidth.

It seems to me that as you go lower in frequency, the inductive reactance
at the feedpoint becomes less and the series stub reactance becomes
greater, so one aggravates the other.

The question is whether the outcome is narrower than desired or available
with other matches.

Because Mosely's explanation contains so much BS, I have no faith in
anything they have said.

A worthy goal.. There's countless schemes for feeding, most developed
empirically, and all probably work about the same, but have some aspect
that is convenient for manufacture, installation, patent avoidance; and
a lot of them are just marketing sizzle (Now! with brigher color paint!
our patented 10 mm bolt with 1.618 mm threads in the Golden Ratio is

available exclusively on our Whiz-Bang model 32 antenna! Worked all 5
boroughs of NY from the top of the Empire State Building on 40m!, etc.)

> fast ground and 15 m height).

Running that model in free space gives a forward gain of 8.13dBi and a
f/b of about 26.5 dB, with a couple of sidelobes at 115 degrees off
boresight at about 29 dB down.

making the change you give, changes the forward gain to 8.11 dBi
(insignificantly different), but the rear lobes get bigger: The side
lobe is now 25 dB down (instead of 29), and the back lobe is at 24dB down.

Still not a bad F/B, though.

>
Changing the length of the elements changes the relative phases and
magnitudes of the currents in the elements. You can have pretty big
changes without affecting gain very much.

However, what *will* go bad in a hurry is front/back or sidelobe
performance. The "cancellation" of the back and side lobes depends on
the phasing of the currents.

So, if the goal is "reasonable gain" in the forward direction and "easy
to build a matching network for" that's a valid strategy.

Just for grins, here are the currents in the center of each element:
5.85m leg 5.15m
R (wire2,seg62) 0.27 + j0.07(0.30< 70) -0.3 +j 0.75 (1.3<111)
De(wire1,seg21) 0.39 - j1.45(0.51<-75) 1.62 -j 1.03 (3.1<-32.5)
D (wire3,seg103) -1 + j0.05(0.45<152) -1.2 -j 0.27 (1.9<-167)

(mag<phase)

A couple things are interesting.. the overall magnitudes of the currents
are lower for the 5.85m version, but that's because it's excited with
1Volt, so the higher feedpoint Z means lower total current.

What's interesting is looking at the relative currents and phases:
The 5.85 has almost equal magnitudes, while the 5.15 has more current in
the driven element, and very much lower in the rear element.

The 5.15 meter has about 143 degrees phase shift from reflector to
driven, and then another 135 degrees from driven to director.
The 5.85 has 145 degree from reflector to driven, and 133 degrees from
driven to director.

That's pretty close in phase, which is why the forward gain is pretty much the same.. the wavefronts line up nicely. It's the different current magnitudes that are ruining the back lobes. A current magnitude error of 10% changes the forward gain by about 0.4dB. But that same error can turn a -30dB side lobe into a -10dB sidelobe.

Aside from marketing BS..

Owen raises a good point. You bring the feedpoint Z from 31.8+j2 to
51+j150. Resonating the j150 with a -j150 is fine, but now,you've
effectively got a resonant circuit with moderately high Q, or, at the
very least, more circulating power between matching network and antenna.

Very good and detailed análisis Jim.

Owen point it is also good, but seems to me it is a little odd biased
by the others claims of Mosley people :>)
I think that if Owen "forget Mosley" perhaps he could give another
chance to the system itself. For example => not all directive antennas
needs a great bandwidth...

However 4NEC2 simulation seem to favor the system we are analyzing.
Adding an ideal reactance of -155 ohms coarsely in the first segment
to the right of the central segment of mentioned provided 4NEC2 model
with lengthen driven element and doing a 13 to15 MHz frequency sweep I
got a lightly increment on VSWR bandwidth of approximately 200 kHz and
a decreasing of VSWR at resonance from aprox 1.5:1 to 1:1 (perhaps for
the localization of capacitive reactance on model?).

Finally, maybe I am also a little biased because my third speculation was viable and that made me feel happy, hi hi :>D

Hi Tom,

It would have been called "coin flipping" by the Indus valley people of Mehrgarh if someone had had the foresight to invent pockets that could hold a dime. Unfortunately, it would be another 6000 years before the first coins were struck. Instead, they flipped mud tablets performing the world's first "binary search:" Is this the solution?

They solved a lot of the state-of-the-art electromagnetics problems back then within two to three tosses. Few disputed their claims (mud is a form of ground) or challenged their accuracies of -50% to +100% for water conductivity (will the Indus overflow this season? - an equilibrium problem of the first order).

It would be that same 6000 years later before algerithms would advance to the point where Archimedes could model equilibrium of water (note its pre-eminence again) in a bath tub. This improved accuracies to -50% to +100% once again (the ancient work had been lost in a flood of the Indus and only recently un-earthed).

Little might have changed since, except that the fluorescence of newsgroup gurus have enlightened modern civilization with advances in accuracies now verging on ï¿½6dB where the pre-eminence of water has been overthrown in favor of photon-stream control. The binary search that was formerly the cornerstone of modeling has been replaced with the unary declaration that is self-proven by having been uttered (or posted to a group that has a vague resemblance to the topic). Hence, the inaccuracies of coins has been wholly removed to yield perfect understanding (within ï¿½6dB, of course).

Bit is not a fixed reactance, it is a transmission line element, and you should model it as that, even if lossless.

That's a fair description of the digital part of antenna design, but
prior to the invention of computing, all such antennas were analog in
nature. The ancient pagans, that found the ideal size and shape of
trees necessary to obtain the attention of the gods were using analog
cut-n-try techniques. Given sufficient time and trees, the design was
eventually optimized.

Somewhat later, the Romans and Greeks discovered that the E and H
directions, the ratio of which was defined by the golden section.
Again, this was not a digital model, but determined with analog
techniques. Once the ratios were accurately determined, the resultant
telephone pole like structure could be used for everything from art to
executions. One of the reasons the Roman Empire lasted so long is
that they didn't have a symbol for zero, thus avoiding the divide by
zero problem. In any case, the design was demonstratively functions,
as installing the design on a hill top, would invariably draw
lightning.

After about a millennium, people started running out of hilltops and
tall trees, and found it more convenient to produce their own
lightning. The previously functional structures were wrapped in
metallic wires and waved around a magnet, thus resulting in home made
lightning. Calculations were again attempted, but since the zero had
been invented, none of the math would work. Once again, civilization
rested on the tried and true analog method of cut-n-try.

Modern antenna design followed the same analog patterns. With the aid
of the analog slide rule, accuracy could be improved to about 2
significant figures. That worked fine until the invention of the
digital computer. Suddenly, 2 sig fig was not enough. The digital
computer could calculate to amazing levels of precision and suddenly
everything had to conform to this standard. Instead of "cut to fit"
and "tweak and tune" it was now necessary to justify the cost of the

new digital computers with absurd accuracies. Good enough lasted only until the next model computer.

So, here we are, debating the relative merits of the umpteenth decimal place, splitting hairs multiple times, and digitally modeling to quantum levels. While useful for justifying the computers, the resultant antennas look roughly the same as the old cut-n-try models designed with an analog slide rule.

Whatever your vision of modeling history, one historical observation remains constant. One must always suffer before enlightenment and this newsgroup provides that function.

>but as dilbert's trolls know, numbers create reality, not the other
way around. if you can't describe it in a formula, it can't exist.
and yes, while the current moves longitudinally along the wire, the
fields are transverse. look at the formulas, they apply to the wire
also. they just get more complex because you have to take into
account the boundry conditions at the interface between the wire and
what is around it... something that freshman physics and calculus are
not enough to handle.

You all time about Maxwell's hypothesis. But Maxwell wrote: "The general
type of a stress is not suitable as a representation of a magnetic force,
because a line of magnetic force has direction and intensity, but has no
third qufility indicating any difference between the sides of the line,
which would be analogous to that observed in the case of polarized
light[2]." From: http://en.wikisource.org/wiki/On_Physical_Lines_of_Force

To explain the light polarization Maxwell assumed that the current in the
wire create the magnetic whirl around the wire (The same for displacement
current in the space).

Maxwell's waves are polarized. Now you know that the dipoles are "polarized"
(not waves).

The Aztecs had a far more accurate model of the calendar than Mini NEC
has for antennas.

As for suffering, the Aztecs also experimented with open-heart surgery
- of a sort. Unfortunately like Art, they never perfected nor did
they care about the recovery phase. There were always plenty of
models (aka prisoners) to replace failures. If you could carve, you
had proven your point and a party generally followed.

A superior technology (conquistadors) took over rapidly. The success
rate of open-heart surgery didn't improve, but the population of
models was enlarged to include All of South America (less Brazil where
Portuguese total-heart bypass was attempted), greater Central America,
and portions of North America.

Basically, we have a theory here that has gutted the heart of RF from
electromagnetics to transplant it with magnetics using a broken
stopwatch.

If you specified it in wavelengths, wouldn't that have a constant
reactance.

The real stub is a fixed physical length, and its reactance changes with frequency.

Good morning (here) Mr. Duffy

It was in meters...

Please, remember the proposition to validate or refute. Once validated
(if it is), then we could think about details

You know, I was not trying to find out if it is the best matching
method but whether it is a viable method. For example: In precedent
post I said I was using a "coarsely" reactance for a basic hypothesis
test because my dictionary suggest that word, perhaps I should have

written: rudely? approximately?

SRI, this is not my natural language and I may not adequately explained my goal...

Inexactness of the solution isn't because the method is digital. The field equations solved by the digital methods simply can't be solved by other methods, except for a relatively few very simple cases. Many non-digital methods were developed over the years before high speed computers to arrive at various approximate solutions, but all have shortcomings. For example, I have a thick file of papers devoted to the apparently simple problem of finding the input impedance of a dipole of arbitrary length and diameter. Even that can't be solved in closed form. Solution by digital methods is vastly superior, and is capable of giving much more accurate results, than solution by any known method.

That difference in choice of basis functions has profound effects on the limitations and quirks of the program, however -- they're quite different for NEC and MININEC. MININEC is, in fact, able to do some things that NEC can't, despite its simpler formulation.

Hi Miguel,

Coarse,
Rude,
Approximate
are the correct forms as adjectives that describe things.

Coarsely,
Rudely,
Approximately
are forms of adverbs that describe actions.

Any of the six words are easily understood in context.

I understand your goal. Newsgroup behavior is about speaking more
completely to the larger audience. Thus, other's will add commentary
to your goal.

Thank you very much Richard I am happy to know it:

When I translate a ham technical article from spanish to english it is
worse because I have not any feedback to check if it has good sense to
english language readers.
I know you say about newsgropus, and that makes very interesting to me
read this. I like the way in that you squeeze the juice of each
topic :>) Thanks to it I have understood very good things from all of
you...

Well, sometime after Archimedes but before today, someone came up with
the idea of logarithms, allow us to talk in dB instead of percentage ratios.

So there have been advances <grin>

In the Mosley case, judging from the writeup at the link supplied a few
days ago, the series capacitor is sufficiently short (a few inches?),
that it's probably safe to consider it a lumped element. Isn't it just a
wire in the middle of a tube.. essentially a coaxial capacitor.

True. Since delta f is small (aprox 2%), considering it a plain
condenser, reactance variation between 14 and 14.3 MHz is from 150 to
146.6 ohm; considering it a transmission line variation is from 150 to
146.8 -worthless-
In the worst case, thinking it as a coaxial condenser could have a
higher error on cable length calculation more than in the reactancev
variation with frequency.

I think: If your assumed numbers were those of the Mosley beam, its
SWR would be 4:1(without losses), and with losses included she would
be ï¿½a very nasty antenna!. I think the ham buyers would not be very
happy with such a poor antenna on both cases :>)

I am not saying that the Mosley antenna has a bad SWR or that is has a low gain.

I am just saying that the explanation they give for their matching arrangement
is not convincing. And this leads me to believe that their matching arrangement
is not equivalent to a simple capacitor in series...

of course dipoles are polarized, dipoles = two poles, if you have two
poles you have to have at least 2 points, and 2 points define a line
and that line defines the polarization. qed.

quantization of every number in a numeric simulation is but one of the
contributions to inaccuracy. the limitations of the physical model is
another, every modeling program i know of breaks the physical thing
being modeled into small pieces, some with fixed sizes, some use
adaptive methods, but then they all calculate using those small pieces
as if they were a single homogonous piece with step changes at the
edges... that also adds to inaccuracies. the robustness of the
algorithm and the residual errors created are a bit part of getting
more accurate results. There is no doubt that numerical methods have
allowed 'solutions' of many problems that would be extremely difficult
to find closed form solutions for, but they must always be examined
for the acceptibility of the unavoidable errors in the method used.

other non-digital methods also have their limitations. unless you are
using the original differential or integral equations and satisfying
all the boundary conditions, your method will introduce errors.
weather that means you represent an odd shaped solid object by a
sphere, or make other geometic replacements that give you simpler
field configurations, you have introduced errors at some level. you
must of course judge these methods by the same way to determine of the
errors introduced by the simplyfied geometry or other methods used are
acceptible for the problem at hand.

Not all modeling uses step changes. Some modeling approaches use a model description that is continuous at element boundaries (at least for some number of derivatives). For example, a cubic spline has smoothly varying values, first and second derivatives.

The tradeoff in the code is whether you use fewer, better (higher order modeling) chunks or more simpler chunks. For instance, NEC uses a basis function that represents the current in a segment (the chunk) as the combination of a value and two sinusoid sections. Other codes assume the current is uniform over the segment, yet others assume a sinusoidal distribution or a triangle.

This leads to a tradeoff in computational resources required: numerical precision, computational complexity, etc. (lots of simple elements tends to require bigger precision)

I think that for codes hams are likely to encounter, these are pretty subtle differences and irrelevant. A lot of the "computational efficiency" issues are getting smaller, as cheap processor horsepower is easy to come by.

that also adds to inaccuracies. the robustness of the
> algorithm and the residual errors created are a bit part of getting

That's why there's all those "validation of modeling code X" papers out there.

I will assume that most here are familiar with Simpson's Rule
Integration. This allows one to compute the "area under the curve" of a
function with a fairly simple algorithm. It's as little as 7 statements
using Fortran. And it is quite amazing how accurate the answer can be
with even just a few slices of the curve from start to finish. If used
properly.

Don't think that seemingly large chunks mean poor accuracy. When the
algorithm is good, and the program selects the chunk size well, the
results can be very close to the true answer.

I recall Simpson's Rule from work about 23 years ago that lead me to
finding more accurate methods in a great compendium of
"Numerical Recipes
The Art of Scientific Computing."
Press, Flannery, Teukolsky, Vetterling,
Cambridge University Press, 1986

which has Simpon's 3/8th Rule, and a more extensive
"Bode's rule... This is exact for polynomials up to and
including degree 5.
"At this point the formulas stop being named
after famous personages, so we will not go
any further. Consult Abramowitz and Stegun
for aditional formulas in the sequence."
The book continues with FORTRAN (my first language) and Pascal (my 9th
or 11th language or dialect by that time) interpretations of a
spectrum of math systems for another 700 pages....

Honest, no name dropping here. In fact this citation neatly
dove-tails with a film I just finished watching (god bless streaming
Netflix) prior to this post that was about some of Cambridge's (and
Oxford's, hence Oxbridge's) noted Dons: Cleese, Idle, Chapman, Palin,
and Jones (with some Yank called Gilliam)
"Before the Flying Circus"

Some of these remarkable academics acknowledged, with gratitude, the
groundbreaking work of Stanley Unwin - on par with the Goon Show.

Somehow all these loose ends tie together here - eventually. One has
only to wait....

nothing is perfect. even radio waves are not perfectly monochromatic
and hence not perfectly coherent either. but they are close enough
that we can tell they are the same phenomenon, they are all
electromagnetic waves and obey the same laws.

Art wrote:
"I just completed an experiment with my antenna optimizer program where I had a dipole in free space and where I increased the diameter until it was close to .003 ohms resistive. What this means is the current flow is right at the surface where there is no skin depth penetration involved and it is close to zero material resistance. This means the total resistance is the resistance of the surface encapsulating particles. The radiation was 35 db in a shape close to that of a sphere."

Ask yourself if the exerimental results are reasonable.

According to Terman:
"Radio waves are produced to some extent whenever a wire in open space carries a high-frequency current. The laws governing such radiation are obtained by using Maxwell`s equations to express the fields associated with the wire; when this is done there is found to be a component, termed the radiated field, having a strength that varies inversely with the distance."

The simple very short elemental dipole has a figure of eight pattern cross section and produces a power gain of 1.5 over an isotropic radiator, which produces the same radiation in all directions. 1.5 = about 2 db power gain as 3 db represents about 2X the power.

"Radiation close to that of a sphere" is close to isotropic or uniform in all directions, the standard for 0 db gain, not 35 db.

About the only asvantage of a fat or cylindrical dipole is broader bandwidth than a thin wire dipole which has the same gain, is cheaper, lighter, and has less wind loading.

One beautiful day if Art keeps trying he may have an original idea that works.

Best regards, Richard Harrison, KB5WZI

>nothing is perfect. even radio waves are not perfectly monochromatic
and hence not perfectly coherent either. but they are close enough
that we can tell they are the same phenomenon, they are all
electromagnetic waves and obey the same laws.

Nobody know what the EM waves are. See what Maxwell wrote: "I propose now
to examine magnetic phenomena from a mecha nical point of view, and to
determine what tensions in, or motions of, a medium are capable of producing
the mechanical pheno mena observed. If, by the same hypothesis, we can
connect the phenomena of magnetic attraction with electromagnetic phe nomena
and with those of induced currents, we shall have found a theory which, if
not true, can only be proved to be erroneous by experiments which will
greatly enlarge our knowledge of this part of physics. " From:
http://en.wikisource.org/wiki/On_Physical_Lines_of_Force

Our knowledge is enlarged enough to say:
Now we can tell that light. radio waves and sound are the same phenomenon
and obey the same laws.

Electric field is along the wire. If antenna has the ball on the end the
electric field is at right angle to tha ball surface.

> Dipoles have nulls at their ends and maxima perpendicular to the

At the ends of the dipole the voltage is doubled (at least).
>

In meantime read this: http://en.wikipedia.org/wiki/Standing_wave

In Maxwell's hypothesis the electricity is incompressible. Standing waves in
antennas are the experimental prove that the hypothesis is erroneous.

See what Maxwell wrote: "I propose now
to examine magnetic phenomena from a mecha nical point of view, and to
determine what tensions in, or motions of, a medium are capable of producing
the mechanical pheno mena observed. If, by the same hypothesis, we can

The transmissing line is in open space.
It seems that radio waves are produced from ends of the wire where the
voltage is doubled (at least)

> The laws governing such radiation are

Maxwell's equations (wrote by Heaviside) are for the incompressible
electricity. Such electricity create the oscillating magnetic whirl. Such
whirls are transwersal.
The Maxwell's hypothesis is erroneous.

Half waves dipoles or shorter are always the two sources of waves. The
pattern is a rsult of interference of them.

The quantum electrodynamics process for the generation of EM waves is
well understood. The electron carriers in the wire are alternately
accelerated and decelerated by the transmit signal energy. During the
acceleration process, electrons absorb energy. During the deceleration
process, electrons emit photons, the quantum particles associated with
the radiated EM waves. Electrons at the ends of a wire dipole are not
accelerated as much as the electrons in the middle of the dipole.

I have an old W9INN (SK) 40/80 Dipole that has worked great; however, I suspect the balan or center feed may be open inside. I would like to know how to test it or how to obtain a replacement.

Anyone know of a source of replacement parts for W9INN antennas?

> resistance is the resistance of the surface encapsulating particles. The
> radiation was 35 db in a shape close to that of a sphere."

> Ask yourself if the exerimental results are reasonable.
Why
Reasonable means no change from the deductions made in the past aka
resistance to change.

An experiment is an action which requires an explanation otherwise
there is no reason to do it.
I had no expectations of what the results would be that I would have
to provide an explanation for.

Superconductivity reduces resistance which could correlate with
removal of fields from that which the current is applied. If this is
correct I sq R suggests
increased radiation. This would appear reasonable
If the fields transferred to a nearby medium whether it be a
encapsulating material or just a nearby substance one has transfered
the problem
to one where the fields in a adjacent material is handled and where
the applied power is applied to a member without resistance.
Is that reasonable ? Yes it is. Explanable is another question. This
is the very reason for any experiment
with respect to education. Reasonable means that
it does not meet expectations which, if we are not willing to think
about, means discoveries are impossible.
First question to ask is superconductivity a reality ?
Second is whether antenna programs are to be trusted?
I did the experiment with purchased material and it gave me the above
results which I am sharing.
So the question becomes is it correct and why is it not correct. First
thing to look at obviously is can a field or fields be removed from a
conductor?
In boundary laws if we don't consider the passage
of static particles that enter the boundary compared to those that

leave the boundary then things become awkward because we also know
that we are taking account of flux transitions.
If Gaussian laws state that static particles can become dynamic then
the answer is that fields can
exist beyond the sphere to which current is applied.
Now that is my personal suggested interpretation of what happens to
provide agreement with the experiment findings. Other interpretations
provided could appear more valid.
I am not equipped to comment on the validity of the computer programs
as Maxwells equations do not explicitly explain the mechanics of
radiation so I leave it to others to provide better answers for the
situation seen above. Yes, I know that the interpretation of Maxwell
is not fully supplied in the books so I invite others to advance
suitable explanations. Is that so bad?

the radiated EM waves. Electrons at the ends of a wire dipole are not
accelerated as much as the electrons in the middle of the dipole.

It was a few weeks ago.
Electrons are decelerated at the ands of the dipole.
Next they accelerate and in the middle (of the oryginal Hertz dipole) the
speed of electrons is constant (no acceleration/deceleration).

In textbooks are prsented all theories and hipothesis.
It is your choose which one do you prefer: EM, photons, QED or like sound.

"QED mathematically describes all phenomena involving electrically charged
particles interacting by means of exchange of photons".

QED is about Photons, not EM waves. Photons have the analogy in phonons. So
radio waves are like the sound.

On May 19, 2:03 pm, "Szczepan Bialek" <sz.bia...@wp.pl> wrote:
> QED is about Photons, not EM waves.

From "QED", by Feynman: "So now, I present to you the three basic
actions,
from which all the phenomena of light (EM waves) and electrons arise.

-Action #1: A photon goes from place to place.
-Action #2: An electron goes from place to place.
-Action #3: An electron emits or absorbs a photon."

Photons and EM waves are the same quantized phenomena, viewed in
different mathematical ways. A single photon can pass through two
slots
at the same time and interfere with itself on the other side.

Extra information
When resonant at 50 ohms resistive the donut shape was evident and
provided by two vortices.
As the resonant value dropped so did the depth of the two vortices
At 5 ohms resistive the vortice depth really started to reduce in
depth.In other words as the vortice reduced so did the skin depth and
where the reduction in vortice volume was taken up by radiation. When
the resonant point was brought to a fraction of an ohm the vortices
had virtually disappeared and the radiation increased such that the
total radiation became a sphere which equated to a maximum radiation
value. Dropping the resonant value below zero ohms removed the
radiation pattern from its normal progression.
This would infer that zero displacement current was generated which
means that particles were only elevated and not projected or
accelerated in any particular direction which thus permits a sphere of
radiation, contrary to that where particles were accelerated in any
particular direction. Note that it is the intersection of two fields
that created acceleration and direction as shown on my antenna page
and with direction the donut shape is retained. Thus this line of
logic supports the idea of a spherical radiation pattern as, with the
absence of resistance so goes the absence of eddy or displacement
current.

The presence of these vortices are used to determine imperfections in
materials during manufacturing processes. Removing the presence of

such is the primary reason for laminations instead of solids in the manufacture of transformers.I am surprised that you are not familiar with the concept of skin depth when at the same time you consider yourself as an expert with respect to antennas. The antenna program I use is
AO Pro purely because it has an optimizer to ensure Maxwell's equations are adhered to as well as accountability for all vectors involved. Planar devices are quite efficient such as the Yagi but planar devices are not in equilibrium which is a requirement of Maxwell's equations! I imagine that with any program you could fiddle with a dipole
construction such that it was resonant at a very low impedance to obtain a progression for radiation
pattern /volume versus impedance if it does not posses optimization abilities. The free EZNEC program probably will be good enough.
As far as vortices are concerned the same two vectors used with antennas are also evident with the Earth's weather system. For instance, a tornado
or a whirlpool presents a vortice by virtue of the intersection of two vectors involved. Remove one intersecting vector and the vortice disappears. This is an example of what Einstein saw with respect to his leanings on the unified theory.

I was in the US Navy from 1962 to 1982 and encountered the venerable R-390A receiver on many occasions. By design, the -390 was equipped for diversity if you manipulated some straps on the rear panel. However, the one time that I tried to use a pair of -390s in diversity mode the results were less than spectacular. I was on a ship and we copied an RTTY broadcast that was being keyed on several frequencies, all subject to QSB. I suspect that the combined audio signal, even though it sounded better (less apparent QSB), was degraded by differing path lengths for the two signals, causing timing jitter on the recovered TTY signal. Whatever the reason, performance was worse, not better.

I wrote: "In textbooks are prsented all theories and hipothesis.
It is your choose which one do you prefer: EM, photons, QED or like sound."

So you prefer the all.
The "like sound" is the oldest and explain the all phenomena.
The new ones: EM, photons, QED explain only some. They are the fantastic
pieces to teach.

My W9INN dipole does not use the W9INN Balun Box. It uses something
made by Bill that looks like an MFJ-918.

Check from the coax connector to each side. I just did this with a Spi-Ro
160 I have been using.
Center to the end of one side was a complete closed circuit. The other side
shield to end was open. From the connector to the coil was closed but nada
on the other side of the coil. So in my case the coil is bad.

To start all you need to test is from the coax connector to each side just
beyond the center connector/balun. W9INN used a 1 to 1 balun
along with a connector. You can used a budwing
center connector then add the balun (2 pieces).
I would suspect the balun first then the center connector. If that antenna
has traps check them also if everything is Ok in the center.

Good luck.

mr. b. you and art should get together. i'm sure his vortices off the ends of his over optimized dipole would work well with your sound model of electromagnetics. he has forced the particles off the dipole by making it superconductive so they should respond like perfectly compressible sound carriers and since they are massless the sound will travel at the speed of light. how perfect could that be! both new theories come together in one big never ending thread where we can all read the bafflegab and have a big laugh behind your backs, or maybe right in your faces. Sorry i've been a bit slow responding, i had a nice trip to dayton, but didn't find any of the unwin antennas for sale, or any sound driven dipoles out in the flea market either... well, maybe next year, i'm sure you'll both be selling those new superconductive longitudinal wave generating magical levitating diamagnetic neutrino hyperwave antennas at bargain basement prices after everyone learns how bad they really are.

Oh that's right, I forgot. You use my god child. I asked Brian to do
that program for 2 or 3 years before he finally did. I was the alpha
tester on it and other of his programs.

You do know that's just MiniNEC, right? With all the problems MiniNEC has included for your computing pleasure.

It's off frequency - low. And it gets worse as the wire diameter INCREASES. Which is what you are doing in your example.

It also doesn't like bent wires, as in things that don't meet at 180 degrees. It breaks down completely at less than 28 degrees.

It doesn't like adjacent segments that are in a ratio greater than 2 to 1.

And it doesn't like adjacent wires that are closer than .23 of a segment length.

Given some of the things you have posted that you have modeled, I'd guess that you break a minimum of 1, normally 2, and sometimes 3 of the above conditions.

No wonder your stuff acts abnormal.

And you are using this tool to attempt to prove your twisted theories about Maxwell's equations? That's like using a chain saw to do brain surgery.

All very interesting Tom but frankly you lack credibility. As with
other posts of yours you do not provide specifics and more than often
express opinions. I personally am as pleased as punch in what I
purchased from Brian and I certainly do not believe he would foist on
the ham community anything but his best. Knowing that he is not
exactly a peoples person I suspect he would not shy from a clash with
you when you distribute your personal opinions. So I can imagine why
such a person like you would jump at the chance to savage another's
personality. For my part I use the program strictly for his adherence
to Maxwell's equations which is the approach that I take. This allows
for an over check most times when ensuring
that arrays proffered meet the condition of equilibrium of each part
and all of the provided
array. I doubt very much you would have strayed beyond the Yagi and
other planar designs when testing, but then you are not short of
claiming anything that may boost your position in life.
Thanks for your operative points offered and I will certainly consider
them within the specific technical confines which you so gently
provided.

Regards
Art

It was his best, but based on MiniNEC. He couldn't change that. He did
tweak things in YO because it was special purpose, but I believe he left
the engine in AO pretty much alone.

> exactly a peoples person I suspect he would not shy from a clash with
> you when you distribute your personal opinions. So I can imagine why
> such a person like you would jump at the chance to savage another's

> personality. For my part I use the program strictly for his adherence

> for an over check most times when ensuring

It adheres to MiniNEC's core. Which adhere to Maxwell no more and no less than that. And it has serious and known shortcomings, which you seem to want to wish away. Brian did a great, hell spectacular, job with what he started with, but he couldn't make the problems with MiniNEC disappear. No one has done anything like it that is available at the prices he charged since then. But the user needs to understand the limitations of the product.

> that arrays proffered meet the condition of equilibrium of each part
> and all of the provided

AO knows nothing of the equilibrium of which you speak.

> array. I doubt very much you would have strayed beyond the Yagi and

> claiming anything that may boost your position in life.

You have no idea what I have done, designed or built. But I would bet I've built more, and that it works better than anything you have come up with unless you copied it from someone else.

Tom I try to provide the specifics with respect to my posts because
without them there can be no discussion. I do get discussions and
generally they
are not as nice as I would like them to be but others do get involved
while at the same time providing worth while comments such as the
continuity of the donut shape which forced me to reconsider. As far as
minninec is concerned I had no other choice since I required an
optimiser but even so minninec surely has its problems the same as
NEC. If and when NEC tries the optimiser aproach I suspect they will
incorporate minninec in some way. As far as the faults you pointed to
I can't imagine not placing segment opposite each other for close
spaced elements or in fact placing much confidence in bent angles in
the area below 30 degrees whether it be eznec or minninec.
When I started to look away from yagi's and planar devices I followed
the standard rules of mathematics with respect to equilibrium and
Maxwell's rules, I was very pleased that the mininec
conformed to my expectations. This however, did not stop me from
getting confirmation else where using NEC4. So again I have no reason
not to trust
AO any time before I distrust myself when I am more than willing to
declare what I did and who I am. The reason I do respond to your posts
is to encourage you to use free speech and thus force you to disclose
what sort of person you are to other members of the group, and not for
its technical content. I have on my page unwinantennas a sample of an
array (diversity array)that conforms to my thinking with respect to
Maxwells equations
which were fully revealed to me by the expansion of

Gauss theorem from static to dynamic in every way,
which provided the evidence of particles as the carrier of radiation.
Since nobody on this group is willing to understand the meanings of
equilibrium in physics or the legitamacy of changing static parameters
to dynamic, minninec did supply the backing for my thoughts in every
way which no other program that was available was capable of.
Have a happy day
Art

And yet you never, ever, give numbers that define your antennas,
excepting the almost planar example antenna. Which doesn't work all
that well, actually.

You have to present some examples of things that actually work well
before you are considered credible.

And given your claims, you are expected to show antennas that are demonstrably better than current designs.

So far you have not done any of the above.

I am going to build an array of 4 stacked dipoles for operation on 2 metres. I would like to know whether the gamma fed dipole has any advantage over the folded dipole, apart from the folded dipole being a tad more difficult to make.

I have heard that the gamma fed dipole has a skewed radiation pattern in comparison to the folded one.

Any thoughts and advice?
Many thanks

Hi John,

You could have heard the same thing said for the opposite design - and
they would BOTH be true.

The devil is in the details, such as how much skew would it take to
bother you? Then there is the question, how much skew before it would
it matter anyway? Some folks sweat over things they couldn't possibly
measure. Worse yet, they would pay more to change things than they
would get back in improvement.

The Chronicles of Arthur Unwin. :/
Delusions of grandeur induced by abuse and misuse of
antenna modeling programs.
Excessive adult beverage consumption may also be
an issue, but I couldn't really say being as I can't give
him a breathalyzer test over the internet...

Heck, I think more than a few of the common programs
have "optimization" routines. Big deal.
I know the freeware MMANA does..
And having played with it a bit, I know you have to take
the results with a grain of salt, and often the results were
worse than what I would come up with manually. :(

Say optimizing a yagi.. I've seen some fairly peculiar
and below par results using the optimization in that
program. Art's blind trust is rather peculiar. :/

Not to mention some of his peculiar theories and notions.
IE: if the pattern of an antenna displays an isotropic
pattern, how in the heck are you going to have large
amounts of gain? The gain would be near zero if using
isotropic antenna as the reference.
Not 32 dbi or whatever number he came up with.
In order to have gain in any direction, a null must form
in some other direction. No free lunch. Sorry.
Of course, Art seems to confuse efficiency and gain, but
that's a chapter for another day.

Art generally ignores efficiency. In his world, equilibrium,
neutrinos, and solar fairy dust particles with levitating vortex
swirls cause efficiency issues to vanish into thin air.
If the vortex swirls start to resemble what you would see
off a Boeing 757 on a moist cloudy day, you have total

equilibrium and obvious 100% efficiency and 87 dbi gain
in all directions.
Tell Jethro to fix the brakes on the truck. We may be moving
soon. :)

Say as when using an A/C fan motors worth of thin wire wound
on a short stick of PVC and supposedly operated on 160m.. :(
But even Art himself claims to almost never actually use the
transmitter in his rig. Being as even a stick of wound wire can
receive halfway well on the low bands, we have a new miracle!
Never mind that some guy tried the same thing about 85 years
ago I'm sure.. :/ It doesn't work any better now than it did then.
Back to the drawing board for prior Art..

No transmit tests or comparison with known benchmarks are
required in the world of Art. The masters sayeth, so it must
be true! Woe to the non believers! They knoweth not what
they do or say!

They have no equilibrium!

Call the patent office, and get the lawyers on the phone!
Load up the truck, we're moving to Beverly Hills. :)
Did Jethro ever fix the brakes?

In the dark recesses of Art's brain, he applied the theory of
reciprocity to this antenna. It receives fairly well, so it surely
must transmit in a like manner.
If only the world were fair.

Next week.. If you run over a neutrino with a Goodyear
Accutread tire, will a puncture occur?
The answer to this question and many others on the next
installment of Art's Chronicles.

"All phenomena", including traveling at the speed of light in a
vacuum? :-)

All without exceptions.
In the space are free electrons (plasma). If you move one of them the next
reacts on it. It is normal pressure wave (electric wave).

It is intresting that the speed of electric waves are the same in vacuum and
in conductors.
In insulators the electric waves travel slower.

Richard Harrison has posted a number of times the comment that systems using folded dipoles are much more robust with respect to lightning and static discharges due to the low impedance path for DC and most of the RF components they contain.

Yep.

As I point out when I give a talk about antenna basics, the isotropic radiator has the lowest possible gain for any lossless antenna, if you consider an antenna's "gain" to be its gain in its best direction. In other words, any lossless antenna has more than 0 dBi gain in some direction.

I make sure I point this out before I introduce very short and theoretically lossless dipoles. A free space dipole has a gain in its best direction of about 2.15 dBi. No lossless antenna can have a gain in its best direction of less than 0 dBi. So what should we expect the gain of a very short dipole to be if we could make one with no (resistive) loss?

Hello to All
Yesterday I took down a small HF beam antenna,for lady whose husband just passed away.
He had bought it last year brand new.At 1st I thought it was a Butternut Butterfly beam,but its not.
The reflector is a elongated triangle with wire around the perimeter of it and has clear tubes for support of the triangle that go into Aluminum tubes of the support structure,in the middle of the triangle is a plastic hub that it all ties into and mounts to the boom.The boom look like aprox 10' long,the driven element has a matching network of some kind that is in a gray 4x4 box,and at each end of the driven element it has a hub with about 8 rods on it,the director is almost the same as the driven but is not split in middle and has the same hub and rods at the ends of it as the driven element.
I hope I explained ok the best that I could do
Any input would be great
Thanks all and have a nice summer
Howard

If you are correct, the feedpoint impedance of a 1/2WL standing-wave
dipole should change from 75 ohms to around 600 ohms (traveling wave
antenna) when installed in free space. Does NASA know that resonant
standing-wave antennas, like 1/2WL dipoles, will not work in free
space because of all those free electrons in free space?

There is a clue in there. Use of the terms does not indicate
correctness, just useage.

While for any given case of Art's antennas, whether the theory, or the actual described antennas - I just don't understand the theory, and the antennas, which are usually explainable by other, less abstruse and more well known methods.

In at least one case, the coil on the end of a mast 160 meter antenna, well, it's a tuned circuit on the end of a stick. No doubt it works in similar fashion to the other antennas of the same ilk, relying on feed line radiation. Nothing new, and no need for new theory in the case that the old one describes it well.

In any event, extraordinary claims require extraordinary proof, and Art is not willing to provide, we are supposed to believe him based on it being him.

Wrong-o-freaking-rama! Just about anything can be explained in some fashion to just about anyone, and the onus is on the one trying to explain. I've never had a problem understanding anything else the experts have offered. That brings us back to my first sentence.

An ordinary proof would be more than adequate. It is the
"extraordinary" proof (aka radiating particles on diamagnetic rods
enclosed in the equilibrium of a faraday shield to induce the
Luxembourg effect) that is probably the surest indicator of deception.

Sal, KD6VKW wrote:
"Wharever the reason, performance was worse, not better."

Sal, thank you for your U.S. Navy service.

My experience with diversity was different. At Radio Free Europe we relayed broadcast programs by HF radio before communications satellites existed.

We used Hammarlund SP-600 receivers in triple diversity. We found most other receivers deficient. Our receiving sites were remote ffrom our transmitting sites to avoid interference. We used UHF for short haul relay.

For HF triple diversity each of the SP-600s was connected via an isolation amplifier with a separate rhombic antenna aimed at its transmitter. Outputs of the three receivers was fed into a Crosby or Pioneer combiner which elected the best signal and rejected the other two.

The horizontal rhombics each required four towers because they were laterally spaced about ten wavelengths apart for space diversity at one of the lower allocated frequencies. We, at times resorted to frequency diversity too.

The receiver operator listened to both of the sidebands of each transmitted frequemncy and selected the better of the two for reception manually.

By selecting the cleanest frequencies and sidebands and using the output combiners to select the instantaneously best of three signals, broadcast quality programs usually prevailed.

Best regards, Richard Harrison, KB5WZI

> reacts on it. It is normal pressure wave (electric wave).

> If you are correct, the feedpoint impedance of a 1/2WL standing-wave
dipole should change from 75 ohms to around 600 ohms (traveling wave
antenna) when installed in free space. Does NASA know that resonant
standing-wave antennas, like 1/2WL dipoles, will not work in free
space because of all those free electrons in free space?

Alternate electric field from the ends of the dipole kicks the electrons in
the space and they oscillate (longitudinal electric waves).

I suppose you are right there Richard. Its just that we don't often get the chance to use extraordinary twice in one sentence very often, I just got carried away.

right, read this carefully from that 1864 note: 'the requirements of
his mechanical model keep him from finding the correct boundary
conditions, so he never does this calculation'. This is just one of
the basic shortcomings of using a mechanical analogy, you can not
satisfy the electric and magnetic field boundary conditions that the
final version of his equations handle properly. while some basic
effects like the interference patterns can be duplicated for both
longitudinal and transverse waves, they are not interchangeable in all
cases and trying to do so will only lead to absurd things like
electrons jumping off antennas or the need for an aether to transmit
em waves.

How much I^2*R loss is there in the plasma conductors of free space?
How far into space does the electron plasma effect extend? If
electrons can flow from a cold aluminum element in a vacuum, why does
a vacuum tube need a special heated cathode?

I built a 2m J-Pole from 1/2 inch copper tubing.
I am going to put a page about it on my website.(HTTP://ai8o.yemiola.net
)
The webpage will have a short history of Zepps and their evolution
into J-poles.
I took pictures during construction showing how it was constructed,
and will post them also.
Does anyone have a current/voltage plot of a J-Pole that they would
be willing to share, so I can post it on My J-Pole webpage?
I have found several diagrams of J-Pole dimensions, (like the one in
the ARRL Antenna Book),but I have not found any Current /voltage plots
for a vertical J-Pole.

In science area are scientists and teachers.
All scientists know that electricity, magnetism and gravity are the same.
Teachers know that the three must be taught seperately. Are you a student?

Maxwell's model is for the aether. But with the two substances: magnetism and electricity.

Your antennas have the blunt tips to prevent the "jumping off ".
The alternate voltage in the ends create the oscilation of electrons in neighbourhood .

Electrons in space are detected. So they are the aether.
Do not you hear on Dirac electron see?

Oscillations are not travelling. Loss are only when something travel between
obstacles.

>How far into space does the electron plasma effect extend?

As far as light do.

>If electrons can flow from a cold aluminum element in a vacuum, why does
a vacuum tube need a special heated cathode?

Also exists the field emission. But it is harmfull for antennas if it is in
form of sparks.
The high voltage kicks the electrons in the neighbourhood.
Probably the electrons flow (and come back - but it is not symetrical)) from
a cold aluminum element. Anenna radiate if VSWR is low. It means that not
all come back.

no, i am not a student, i am an engineer by training and scientist by
title. where in maxwell's equations is there an aether?

not all antennas have blunt tips, and electron's don't just 'jump off'
an antenna.

no, just because there are electrons in space doesn't make that an
aether. there are electrons flowing in vacuum tubes, that is a
current, not an aether to carry em waves.

so over a period of time if the electrons keep flowing away from an
antenna it should become positively charged. and the longer it
operates the higher the charge. unfortunately this is not the case,
antennas do not give off electrons any more than they have magical
levitating neutrinos like art prefers.

>no, i am not a student, i am an engineer by training and scientist by
title. where in maxwell's equations is there an aether?

Maxwell's equations are wrote by Heaviside (engineer).
Maxwell did the aether model and proper math.
Teachers often use big names to support his program teaching.
The same is with Ampere. His name is used to support the magnetic whirl.
For Ampere the magnetism is an illusion. It is the electric field of moving
charges.

>not all antennas have blunt tips, and electron's don't just 'jump off'
an antenna.

Whe they are? The reflected wave is weaker.

>no, just because there are electrons in space doesn't make that an
aether. there are electrons flowing in vacuum tubes, that is a
current, not an aether to carry em waves.

The same is in conductors. Currents are DC or AC. Maxwell's displacement
current is the AC (oscillating).
In Maxwell's aether the current in the wire oscillate in phase with the
displacement current in the aether.

Why are you the slave the only one hipothesis. The "like sound" is the
theory.

In textbooks no statements which one is correct. The all are presented.

Is antena grounded?
All circuits are closed. The receiver antenna also do not become negatively
charged. The Earth closes the circuit.

>antennas do not give off electrons any more than they have magical
levitating neutrinos like art prefers.

I am using only old theories proved by experiments. Art is probably trying
to do the new.
The same was with Maxwell. He did the new. May be that Art's hipothesis the
teachers adopt to teaching.

Because of comments made I decided to abandon the idea of increasing
the diameter of the dipole which really is a bit off the wall and
decided instead to change frequency applied to obtain a low to near
zero impedance. This approach did not result in a truly spherical
radiation pattern and nor did it remove vortices ! The pattern when
cut always revealed a figure 8 somewhere. Never the less, peak gain
produced by the program always produced a larger volume pattern when
impedance was a minimum. This certainly implies that because of the
loss of skin the element impedance was lowered and thus the radiation

would increase. Of course it depends on the observer to interprete observations where others may well differ.(A sure certainty in this group)
I am beginning to see an analogy between radiation elements and water, where water being diamagnetic would attract particles. Looking at it in radiating terms, the current would flow within the intersection point outside the water and propel the individual particles from or part of the skin which really is an encapsulation surface of a material other than water. Since mass inside the boundary does not change because of instant replacement the boundary mathematical approach would still hold.
Of course, if the skin was actually made of particles the addition of soap to the radiator surface would render it immune to radiation if bubbles were not created thus leaving a diminishing surface area of broken skin.Hopefully I have supplied enough material to anger those who are sure they know all about radiation and thus provoke them to finally declare exactly what is happening in a scientific manner ala details, details,details
Regards
Art

As mentioned earlier, most of the stuff is old hat to me - but I really look forward to dig into the chapters concerning tx output impedance. A highly controversial subject for decades.

antennas do now have to be grounded. how are antennas on satellites
grounded?? do satellites become massive positive charges in space as
they keep shooting off electrons... again, this is going no where,
when you have read another hundred years of science and are ready to
believe what has been well proven over that time period maybe we can
have a conversation.

Is that a good example of what you call conversation?
Waves and wavelength !!!
Talk with Mister B?
I would do that at a drop of the hat if the outcome was that you
wouldn't engage me in conversation for a hundred years as you promised
him.
I left you a clue with respect to water and the
collecting of Neutrinos but again I over estimated
your interlect
I don't think I can go much lower, you as a person has already hit
rock bottom.
Hey a question for you. Richard lives alone, so does Kotar .Possibly
the other regular hacker also. Would I be correct that you also have
to live alone as you seem to fit the standard model of driving people
away?

So desperation is setting in now. He is grasping at straws about which
he has no knowledge.

Let's try a similar useless tactic!

Have you stopped beating your wife Art?

Tom I just can't see you holding your tongue or being civil for any
length of time! It is quite obvious that you have to live alone. Me? I
just celebrated my 50th anniversary with my wife. Monday we all
celebrate my daughters wedding anniversary where all the tribe will
appear. Another great evening on the horizon. Eat your heart out. And
yes, you called it right, your comment was a useless tactic.

Just as useless as yours, since you know nothing of what you speak about
myself and others. That was my point. Duh.

1641. Radiating coils

Newsgroup: rec.radio.amateur.antenna
Date: 2010-05-23 02:17:18 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <c873b705-6a32-4998-b491-80e3ce15a8af@m4g2000vbl.googlegroups.com>
Source record: 9841

I just modeled two coils counter wound and one inside the other as a complete closed circuit , end fed. Counter winding is quite the norm with special purpose machinery to prevent inter tangling of coils when compressed.
With the coils wound opposite to each other
it made quite a nice antenna when placed on a flat plate. Beam was pencil shaped without side lobes and sensitive to all polarities.Thus any such dishes could be used for 'point to point' using any type circular polarization. Smaller in size compared to other designs is rather obvious. Where Kraus determined such an antenna single wound form demanded a certain angular pitch such a requirement is not apparent with this design. Kraus assumed a certain pitch was required when wave composition clashed, but the opposite happens when particles vectors add. Another example of particle versus waves disputes.It also confirms Maxwells equation by removing the effect of lumped loads which was not included in his equation as was not the stipulation that a radiator must be straight.

Caution:
Above details not yet "printed" in a book so it must be considered questionable.
Regards
Art

I imagine the beating of a wife would procede the sessation of the
above so you would know nothing about the latter until desertion came
about.
Some time ago I saw a man argueing with himself
which was the mirror image of himself as he looked outside. Is that
where you get your experience from
and your need to win at all times?

Is that how your ex wife characterised you after you challenged her
every day after day? I start a new thread in the hope of getting rid
of you. But when I talk antennas you turn to trash because you know
nothing else other than being a hate full and evil person . Read your
own past postings some time and characterise the person behind what
you read. Not very pleasing right!

sorry, last reply have real antennas to work on today. it was in
between them that the aether was pretty well shot down, you like
wikipedia, go read http://en.wikipedia.org/wiki/Michelson%E2%80%93Morley_experiment
and think some more. dirac was trying to resurrect the aether, that
doesn't make him any more correct than you or art... even the best
thinkers have some bad side trips, the best of them know when to admit
they are on a dead end.

I have one I made years ago that is similar, so I can describe it for you.

Materials needed - about 32m of wire, light plywood (I used scrap),
365pf (or anything close) capacitor, connector of choice.

My box is made with 127cm by 13cm plywood pieces joined as an X, which
will give you a 90cm square box. The dimensions are not very critical.
Drill 10 evenly spaced holes near the end of each piece. Thread the
wire through the holes until 10 turns are in place. You will bring the
2 tails of wire in to a point near the center of the X where you have
mounted the tuning capacitor. Solder the tails to the capacitor. Drill
2 holes in the end of each piece just inside of the 10 turn loop for the
pickup loop and thread a 2 turn loop into place. Run those tails to a
point near the center of the X where you have mounted your connector of
choice. Solder to connector.

Connect your AMBCB radio and tune the capacitor for max signal strength.
Enjoy!

Vary size of box, number of turns in loop, and value of the capacitor
for other bands.

When I was in college, I observed a stream of electrons emitting a glow that traveled at the speed of light to my eyes which evolved to detect photons, not electrons. Since photons can do that, why is there a need to introduce the concept of invisible, undetectable, massless, virtual electrons in free space? What is the electron density of free space?

An "infinitesimal," center-fed, linear dipole has a peak directivity/
gain of 1.5, or 1.76 dBi. Getting any r-f energy to flow on it takes
some real heroics, though.

Havent seen one of those in years. Made one when I was a kid in High
School. It was my project in woodworking and physics class.

between them that the aether was pretty well shot down, you like
wikipedia, go read
http://en.wikipedia.org/wiki/Michelson%E2%80%93Morley_experiment
and think some more.

The aether of Lorentz was shot down. Michelson in his famous experiments in
1887 and 1925 (with Gale) proved that the aether rotate with the Sun but do
not rotate with the Earth. Such model of the aether was made by Stokes, the
chamption of the aether.

Lorentz aether was motionless. You know that the Sun rotate. Why the plasma
do not?

The evidences of that are collected by A. G. Kelly:
http://www.worldnpa.org/pdf/ebooks/Kelly%20-%20New%20Theory%20of%20the%20Behavior%20of%20L
ight.pdf

> dirac was trying to resurrect the aether, that
doesn't make him any more correct than you or art... even the best
thinkers have some bad side trips, the best of them know when to admit
they are on a dead end.

Maxwell was full of doubts.

The aether is shot down from teaching program. The plasma is included.
If somebody do not like the "aether waves" he can use the "plasma waves" or
something else..

I don't think a pursuit of destroying Ohms laws is going to prove
anything.Preservation of time is a must with respect to accelleration
of charge. Would it not be better to operate within Ohms law with a
dipole of "near" zero resistance and then apply a time varying current
from one resonant frequency to another.You then obtain a trend of the
change in volume of radiation. I suspect that the maximum radiation
volume could be reached prior to zero impedance dependent on the
particle transfer and replacement time. Working within existing laws
and environments narrows the variables and narrows the scope of the
eventual debate around the findings. The subject is determination of
maximum volume of radiation which has nothing to do with "gain" using
existing definitions.I see nothing unreasonable in using a computer
program to extract data provided by changes of applied frequency.

max volume equals 0dbi gain, by definition. not very practical and
hard to achieve in a real antenna. for most 'normal' applications we
have some kind of preferred direction so directional antennas from
simple dipoles to big dishes are more useful.

ah yes, that ugly little thing called mass... because electrons have
mass they can not travel at c, therefore they can not be the carriers
of electromagnetic radiation. also, it is well known that photons
have no rest mass and no charge, both of which disqualify the electron
also. you should really talk to art, he is much closer with his
magical levitating diamagnetic neutrino.

Hi Mister S
Thank you for supplying reference for the article in the phylisophical

journal. Most of it is beyond my interlect
but a quick review show that the tenents of his explanation
are based first on the requirement of equilibrium
That particles is the center of discussion
That vortices are present to provide a displacement force
And the connection between electrostatic and light
functions. Nowhere do I see reference to Gauss law of statics and the
progression to a dynamic field which makes
his paper some what astounding for him to come up with this paper
without these clues that have been hidden for so long. I intend to get
a print out of all four portions of this paper in the hope I can
cherry pick some portions that I can understand from the paper. As
always one of the most important things are the responses from his
peers which
usually are accompanied by science analysis rather than relyinging on
base intuitions without supporting facts from the ham community.
Thanks again
Art

Oh my. ! The above is the silliest thing I have heard in a long while,
but I am very glad you presented it
as an example of your private analysis. It shows that tho free speech
is viable what is contained in the enunciation is not necessarily
anything other than trash. And I just love that position of yours
"it is 'well known' that photons have no rest mass and no charge".
Don't you have to repeat that a 1000 times before it can be considered
true?

As they say, "Suck it and see" (especially if it's easy to try).
Keep the feeder as far as possible from the filing cabinet (rotating it,
if you can). [No, not the filing cabinet.]

If you don't try it yourself, and report back here what your findings
are, in six months from now, this thread will still be going strong.

Got a station antenna setup. I have twinlead up to 140' per side dipole. I have a desk, facing a wall. Window over to the right. Right now, I have coax coming out of my antnenna tuner, going outside, through the window, to a setup to feed balanced line.

For years, I've thought about what would happen if I brought balanced line into the house.

I've got a metal filing cabinet between window and ham shack. I'd have about 5' of line from my tuner, going around the cabinet, and finally getting to the window.

How much performance degradation would this give me to do it in spite of the metal cabinet? I know for years they say: don't let twinlead come near metal objects. This would be doing that. Wonder how much degradation I'd suffer if I did that?

Probably none. Performance might actually increase slightly if the
coax to twin lead connection is lossy. I'm not a fan of running coax
to
twin lead. If I use a tuner, I run twin lead or ladder line the whole
route.
The "twin lead near metal" issues are often overblown.
Like Ian says, try it and see what happens.

$137.50... Dang.. Maybe I should start selling loops.. They sure
seem to be proud of them when they apply the price tag.
This is my version of the same appx thing, except using a
simple PVC frame. Can be built for chump change if you have
an old BC variable laying around. If not , the caps can be
bought on the web.. I scrounge mine out of old analog stereo
receivers, radios, etc..

So much so that neither of you noticed that the article is scanned and ocr'ed from somewhere resulting in none of the equations being faithfully represented. For most I would expect this to result in difficulty understanding the principles presented.

Art, is there any chance your high observed gain is because antenna has very low impedance that the currents may be overly elevated from the voltage source used in your model?

Low impedance leading to higher current leading to higher fields being generated leading to higher perceived gain.

If you can choose antenna parameters that result in negative resistance, does this really mean your model is working properly under the conditions you are using?

Art,

Please enlighten us.

What is the mass of a proton at rest?

Please quantify the charge of a photon.

much is beyond your intellect... however you should note that gauss's
law wasn't published until about 6 years after that article, so it
would be surprising if it was referenced. that article is also well
before maxwell had published his works that contain his completed set
of equations describing electromagnetic fields... so it is not
surprising that some of what is in there was undoubtedly incorrect
guesses and suppositions based on earlier observations.

For my 80 meter dipole, I have 92 feet of twinlead running around the
roof, and through the window, to my tuner -- it passes a few metal
pieces here and there, and I can't see any problems. I'd say give it a
try -- it's the only way to find out.

I use one of the MFJ window feedthrough panels to get the twinlead
indoors -- they work very nicely.

I have not printed the article as yet and I admit that I had not noted
the earlier publication date. I thought the publication was just one
year old.
I believe it to be interesting enough to get a print out but it will
be difficult to get a full list of comments
which usually as interesting as the article itself.

Joe, I have not seen a description of a photon and I believe a sample
is yet to be maintained.
Possibly the accelleration of a neutrinos and the resulting collision
will separated the charge from the neutron so one can see if it is
accompanied by a morsel of mass. I say that because as the neutrinos
is the smallest mass known which leads to the maximum speed of light.
Thus collision should not be able to separate the neutrino alone and
only separate attatchments.
But my readings on the subject is some what limited.

Certainly if you consider I sq R and the removal of losses made by
penetrations into the metal . But there are other considerations such
as the swamping of diamagnetic action in air after near removal from
the metal itself because the change in eddies strength changes every
thing.
I cannot explain the mechanics of what is actually happening and can
only be guided by what the programs infer. Intimate discussion of the
above is more than welcome. Especially the realization of maximum
radiation determined by the time needed for the replacement of the
ejected particle which probably occurrs before minimum impedance is
reached. I cannot imagine the addition of zero or negative values in
the equation since only the contents of the boundary is relevent in
accountability for all forces as I see it based on
Newtons laws. Joe your comment are the first review that is willing to
discuss the merits of my work and I sure welcome it so that closure
can be reached

> OZ7S Sven

Hello Sven,

Glad you received your copy today. To pique your interest in tx output impedance, Chapter 19 will do that for you, especially Sec 19.14 on Page 19.22. This section describes in detail, in fourteen steps, how the output Z is measured.

I've seen a lot of discussion on this subject, and most of it shows that many who discuss it don't have a clue to the correct answer. Which is why I have made many measurements of the output Z to determine the truth.

The output Z is determined principally by the proper adjustment of the tank circuit with respect to the load. I'm talking now only about tube amps with pi-network tank circuit coupling the amp tube to the load. I

cannot comment on solid-state rigs, or those that have no tuning adjustments.

There are those who believe that the output Z = 50 + j0, and there are those who believe the Z is much higher. Here's what really happens. With any practical grid drive, load and tune the amp into a 50 + j0 dummy load to deliver all the available power. In this case the output Z of the amp will be 50 + j0 ohms.

Now add 50 ohms of inductive reactance to the same dummy load. The result is now a load impedance of 50 + j50 ohms. Now reload and retune the pi-network to again deliver all the available power into the new complex-impedance load. The new output Z? 50 - j50 ohms, the conjugate of the complex load impedance. In other words, to determine the output Z of the amp, simply load it into an impedance of known value such that all the available power is delivered at a reasonable drive level. The output Z is then the conjugate of the load impedance.

You say you want proof of this simplistic procedure? Fine. It's all right there in the fourteen steps in Sec 19.14 that describe the entire measurement procedure. I'm sure you'll find the procedure enlightening.

Walt, W2DU

Can I rain on your parade? Light is just super high frequency RF. There
is no such thing as a photon but scientists still use that to explain
things in human terms for the unknowing masses. The best way I can
describe a photon is that it is one wavelength of light at any given
wavelength or frequency if you will. If a star or even our own sun gave
off photons at the rate of burn then it would very soon be an ex-star.
There are very few people who can think at the needed level for this
kind of thing, so let the argument continue. Really silly thinking that
there are red photons, green, yellow, etc.

Exactly. Imagine a tornado which is a macro scale version of the
vortice seen as a displacement current
as a series of capacitors along side the current flow
within which there is circular flow. This is no different
to the laminar flow in a firemans hose. Put projections inside the
hose and you can get multiple vortices because of the lamina
friction.You probably have heard of "curl" with respect to antennas
and yes that is described with respect to vortices. So it is not so
far out to see a tornado
as a cloud enclosed by neutrons in terms of a skin tension. This all
goes back to the release of a small particle from the boundary
enclosing the big band
where rotation is applied to same via the levered fracture in the
boundary as it momentarily loses equilibrium. For the above tornadoes
are seen as the swirling action between capacitor plates comprised of
ground and the upper layers. The capacitor plates perform the same
action as a "idler" wheel so that ejected rotations of particles have
the same spin.
Review vortices if only to get a physical idea how the term "curl"
fits in with respect to lamina flow which you can then expand to
magnetic lines or field of a magnet for a better understanding of
transitions. Everything on Earth can be described by the two vectors
created at the big bang down to the two vectors of gravity and
rotation where rotary flow introduces lamina slip and the adherence to
Newtons laws including his equations for acceleration. All the above
is thoroughly seen under boundary laws which are centuries old, when
static fields are transformed into a dynamic field. Nothing new, no
new laws or equations but just a different method of connecting the
known dots determined by past physics to produce a closed circuit
similar to the tank circuit in parallel

1683. new question (from "system degradation question")

Newsgroup: rec.radio.amateur.antenna
Date: 2010-05-24 05:02:16 UTC

I'll be using 100 watts SSB/CW, and have about 75' of twinlead up to antnenna feedpoint.

You've got me going to do the "system degradation question": I'll run twinlead to the shack, in spite of the file cabinet.

Now, yes--I can do just fine manually changing my antenna from ladderline fed to putting it on 160 by jumping both ends together and letting it work against ground. Long counterpoise in place. Then, putting it back as twinlead dipole on 80m up.

What's the new question? I normally would go from 160m up through 15m. If I just used the jump both ends together and feed long wire, which ant will be better?

Basically, it's whether a long hat vertical would be as good as using my twinlead as dipole on bands including 80m and up.

I can certainly keep the antenna twinlead fed dipole, no problem. Just curious.

On most bands it will operate the best fed normally as a dipole.

Thank you for supplying reference for the article in the phylisophical
journal. Most of it is beyond my intellect

Do not worry. Maxwell is an excellent writter and his English also.
Everything is wrote in English and next in Math. The math is to calculate.
We do not calculate enything.

>but a quick review show that the tenents of his explanation
are based first on the requirement of equilibrium
That particles is the center of discussion
That vortices are present to provide a displacement force
And the connection between electrostatic and light
functions. Nowhere do I see reference to Gauss law of statics and the
progression to a dynamic field

Maxwell described the rotational oscillations.
Gauss dynamic field is simply the longitudinal oscillations (like sound).

>which makes
his paper some what astounding for him to come up with this paper
without these clues that have been hidden for so long. I intend to get
a print out of all four portions of this paper in the hope I can
cherry pick some portions that I can understand from the paper. As
always one of the most important things are the responses from his
peers which
usually are accompanied by science analysis rather than relyinging on
base intuitions without supporting facts from the ham community.
Thanks again

It is math for it (Doulong). If a cristal is kicked it radiate diffrent
frequences. But not all and for a limited time.
Higher frequency bigger energy. But such packets are longer than one
wavelengh. It is a coherency of radiation.

>If a star or even our own sun gave off photons at the rate of burn then it

Some substances emitt only one or only a few wavelengh. Sodium emits yellow.
(Sodium emitts yellow packets?).

While the analysis of transmitter output impedance in Reflections is
flawed,
experiments (claimed to be repeatable) described in Reflections appear
to
support the conclusions of the flawed analysis.

It would be highly valuable if the results of these experiments could
be
explained in a manner that aligns with established understandings.

Such an explanation might start by describing the circuit conditions
that
result from following the manufacturer’s tuning procedures. After
all,
these usually depend on measuring currents and voltages so are only
indirectly related to power. Perhaps the resulting conditions are not
as they are usually assumed to be.

Try as I might, I have not been able to derive a mechanism to explain
the observations in Reflections. But the explanations offered in
Reflections require large chunks of linear circuit theory to be
discarded,
so this does not seem to be an appropriate path.

On an old tube transmitter, e.g. a Globe Scout, when the manufacturer
specifed a particular grid current and a particular plate current,
does that imply a particular single resistive load line for the final
tube? Why were those particular grid and load currents chosen? Maximum
efficiency? Tube life? Minimum distortion?

Excellent questions. I have often wondered if the manufacturer's
tuning
procedures had anything to do with maximizing output power transfer,
or
were they, in fact, optimizing some other aspect.

Keith, would you please elaborate on why you believe my analysis of transmitter output impedance is flawed? And what is the basis for your belief that my explanations in Reflections require large chunks of linear circuit theory to be discarded. Could it be because you consider the source resistance in the transmitter to be dissipative, as in the classical generator? If so, you must be made to realize that the source resistance of the transmitter is non-dissipative, which is the reason that its efficiency can exceed 50%.

Or are you considering the output characteristic of the transmitter to be non-linear? This is not the case, because the effect of energy storage in the tank circuit isolates the non-linear input from the output circuit, which is linear as evidenced by the almost perfect sine wave appearing at the output of the tank.

One last question: Are you basing your dissatisfaction of Reflections from reviewing the 2nd or 3rd edition? Chapter 19 has been expanded in the 3rd edition, in which I presented additional proof of my position on the subject that you should be aware of. If you haven't yet seen the addition that appears in the 3rd ed, please let me know so that I can send you a copy of the addition. Also include your email address so I can send it.

Keith, you are the only person I know of who appears to have found flaws in my presentation on this subject. Which is why I'm anxious to know exactly why you believe my presentation is flawed.

The longitudinal electric waves (electrons oscillations).
The sound waves are also longitudinal (air partcles oscillations).

The theory is from XIX century. It is not mine.

But remember what Bill wrote: "There
is no such thing as a photon but scientists still use that to explain
things in human terms for the unknowing masses. The best way I can
describe a photon is that it is one wavelength of light at any given
wavelength or frequency if you will."

For light the photon has about 200 wavelength.
Radio wave "photon" is as long as transmitter works.

That explains why UV is harmful, higher frequency, while IR at longer
wavelengths is just heat.

Agreed.
That is why LED's emit at only one wave length. It just depends on which

elements are in the LED formula.

I'll give you a partial agreement on this one. The rods in our eyes have
peak sensitivity at Yellow/green. There was a guy, a long time ago who
said he could detect a single photon in a very dark lab. So, if a photon
is anything anyhow a particle how could he see it since the equipment
was set up to radiate into a detector. It may not be in our lifetimes
that the true nature of light is discovered.

The cones cannot detect single photons. It takes many photons to
activate the cones. It only takes one photon to activate a rod.
Unfortunately, the rod is more sensitive than the rest of the path to
the brain so it takes about 9 photons to result in an impulse to the
brain.

Just use the dipole as is on 160. I had basically the same setup with 63
foot legs on
an inverted vee and worked plenty of 160 stations. Try it -- if you don't
find it
satisfactory, then you can always try something else. System degradation is
usually
far less than theory would have it.

1705. Question about "Another look at reflections" article.

Newsgroup: rec.radio.amateur.antenna
Date: 2010-05-24 20:06:19 UTC
From: lu6etj <lu6etj@gmail.com>
Message-ID: <62702483-6d3c-43e0-aa8b-0cff735a387d@e28g2000vbd.googlegroups.com>
Source record: 9705

Hi all. I have a doubt about if this text from "Another look at reflections" reflect the author ideas.

"Laboratory and experimental work often requires holding incident voltage constant with variation in loading. A constant-voltage source is usually obtained for this purpose by inserting a pad having 15 to 20 dB attenuation between the generator and the line to absorb the reflected power, preventing it from reaching the generator where it would alter the line coupling and cause the generator output voltage to vary. Because of the absorption of the pad, the generator sees a nearly perfect match for all load conditions and all reflected power is lost - but these are laboratory control conditions required to obtain valid test data."

For example this part => "by inserting a pad having 15 to 20 dB attenuation between the generator and the line TO ABSORB the reflected power"

¿Absorb the reflected power or amortiguate the effects of variyng load impedance?

As I understand it, even without a conjugated match the reflected power neither returns to the source (Thevenin equivalent source).

I give the following example: If we load a generator directly with a resistance of 10 ohms, without any transmission line, there are not traveling waves interfering, therefore there are not stationary waves, there is only a impedance mismatch affecting the source voltage ¿OK?. If then I load it with a line of half wave finished in the same 10 ohms resitance, the generator "will see" a 10 ohms load, and it will behave identically as it made it with the original "direct" load.
In both cases there is not reflected power that it can return to the generator...

(I admire Walter's work and this consultation should only be read as a question, not as a criticism)

Thank you very much in advance.

I would not refer to the cascading of a practical source with a 15 to 20dB attenautor at a 'constant-voltage source' as Walt did above.

A Thevenin source with Zs=50+j0, with varying load impedances, will always have terminal v/i such that the Vfwd component of a traveling wave decomposition of v is constant. I give the explanation / proof at http://vk1od.net/blog/?p=1028 .

Even if a given source has Zs not equal to 50+j0, a sufficiently large cascaded 50 ohm attenuator will result in a combination that is very close to the ideal Zs=50+j0, albeit at lower level. This is a common technique for 'standardising' the equivalent source impedance of a source.

That is how it works. They have to produce some results for their
funding to continue. I remember when they tried to explain that
everything was made up by quarks. That could possibly explain Neutrons
and Protons, but what about that poor little electron??
Also how come a puny electron has such a charge that it roughly equal
the charge on a (relatively) huge Proton??
There is a lot of understanding to be done yet.
1. What is the speed of gravity?
2. How does gravity propagate through seemingly empty space?
3. How can a magnet attract in the vacuum of space?
Many more questions than answers.
I don't think those questions will be solved until the median IQ reaches
about 130 and not 100, but I am not holding my breath over that ever
happening.
Something for people to think about.

Hi Brian:

When dipoles are mounted to the side of a tower or metallic support,
the gamma match allows the impedance matching to a 50 ohms
transmission line at the optimal distance from the mast to obtain the
typical diagram of the "ofsset." configuration.
To adapt the folded dipole impedance only appealing to a 4:1
transmission line balun it is necessary to bring them near enough to
the tower or conductive mast and so the radiation diagram is no longer
the one that habitually we imagine (+9 dB front, 3 dB back).

Thank you for your answer Owen (but I think that it doesn't answer my specific question, possibly because I am not able to express it well due to my translation to English).
.....
I agree with what you say in your answer and several things you write in your good article "Is Zs of to HF ham tx typically 50+j0? ".

For example that for an idealized Theveninj generator, the incident power is independent of the load impedance (net power Pf-Pr not)
(If an impedances adapting device is inserted between the line and generator and we insert directional wattmeter between the matching device and line, of course Pf varies and Pnet also do it).

Regarding that output impedance of a rig be quite near to 50+j0 I think that depends on the concrete design; such a condition is not necessary and in my opinion neither optimal.

Best regards

I spoke to some physicists at the Fermilab accelerator at Batavia ILL
a few weeks back and it was surprising to me how often the statement
was made "that is out of my expertize". Seems like they are trained to
think in a tunnel out of the hearing and contact of others.Considering
the amount of funds they collect their sparse achievements as noted in
their weekly news letter sure does not impress me a bit. How many

times have we heard
"we hope that "if" we are successful it is possible that it could lead to........"I look for a barrage of such statements in the future about the difficulties of finding Higgs field where it is now felt to be of virtual form without mass and possibly out of range!

Hi Miguel,

Problems arise from qualitative statements or questions instead of
quantitative statements or questions.
>output impedance of a rig be quite near to 50+j0
is a quantitative fact (depending upon the qualitative "near"). A
fact can be measured and compared by in dependant and objective means.
>in my opinion neither optimal
is a qualitative judgment. A judgment is only as authoritative as is
the authority making it - and even then it comes at a discount. We
get many judgments here by folks with little authority (and such
judgments are usually adorned with anti-authority messages).

I have measured the characteristic Z of my two transistorized HF rigs
by different methods that agree in their results. I have also
measured the Z of active loads that employ the same circuitry found in
power sources. The values of Z for my HF rigs wander from 35 Ohms to
75 Ohms. The variation is a function of
1. frequency;
2. power;
3. which of the two is being measured.

What is notable, for those values that are furthest from 50 Ohms (the
design goal), my rigs experience issues (instabilities, poor
efficiency, distortion...).

The variation by frequency is found at the margins (at the ends of the
HF band).

The variation by power is found in inabilities to maintain a constant
power deliver in every band - which weakly correlates to Z offset from
50. Variation by power also defines Z. Low power operation is not
going to give you a 50 Ohm source (the manufacturer designs Z for
rated power).

The variation by set is due to different capabilities: one set is
capable of 150W, and the other 100W; thus the first is more robust. As
these variations of Z are not remarkable, trying to turn them into
quantitative efficiency results are speculative at best (common
designs are not optimal by any stretch when you add in the

complication of modes).

This resolves quickly in measurement - no need to wonder unless it
offers some secondary benefit of not measuring things.

An alternative is to simply examine conventional design
considerations. One can add to Plate current by throwing a lot of
power into the grid. More plate current yields more output power
results, but grid lifetime plumments.

One can do innumerable things to force an artificial outcome that
strains to prove a distorted logic. Examining a suite of sources, in
initial conditions that are average for their application quickly
reveals a common design paradigm.

******

The fundamental answer to your question is the manufacturer ultimately
designs for market domination, or maximum investment return (the two
don't necessarily converge). Thus the marketplace gives us a spectrum
of choice and the norm of the distribution reveals cautious design
that has its eye on a value exchange expressed in money. THAT is the
only optimization you can expect = in an honest barter, you get what
you pay for.

No problems there. There has been much confusion in this area and
anything
that reduces this confusion is beneficial.

> Or are you considering the output characteristic of the transmitter to
> be non-linear? This is not the case, because the effect of energy
> storage in the tank circuit isolates the non-linear input from the

> sine wave appearing at the output of the tank.

This may be the root of my disagreement. Certainly the output can be
an
arbitrarily perfect sine wave, but this simply depends on the
characteristics of the filter and not on whether the system is linear.

But the way the filter transforms the impedances is the crux of the
issue.

It is my understanding that the input impedance to a filter can be
computed by starting with the load impedance applied to the filter and
then, using the rules for series and parallel connected components,
compute the way through the filter until reaching the input and the
result is the input impedance to the filter.

Similarly, the output impedance of the filter can be computed by
starting with source impedance driving the filter, series and
paralleling
the components until reaching the output and the result is the output
impedance of the filter.

The desired impedance for the input to the filter is that impedance
which
produces the desired load on the tube. And the component values are
computed to produce this load on the tube when the correct load is
attached to the output.

For the output impedance of the filter, the question then becomes: What
is the source impedance driving the filter? If the source is constructed
as a Class A amplifier, then it depends on the controlling device, and
for the simplest of circuits would be Rp of the tube. (Just for clarity,
in this discussion Rp is the slope of the plate E/I curve with constant
grid voltage. In an ideal tube, these lines are equidistant apart and the
slopes are the same. Real tubes, of course, are not so well behaved, but
this should not affect the basic discussion.)

Since the component values for the filter were chosen to provide the
optimum load to the tube, and the optimum load value has no relation to
Rp, there is no reason to expect the filter will transform Rp to be
the conjugate of the load impedance.

For amplifiers where conduction is not for 360 degrees (Class AB, B, C),
the controlling device is no longer time-invariant so the rules for
linear circuit analysis no longer apply. None-the-less, for example,
consider a Class AB amplifier where the tube is only cut off for 1
degree. This short cut-off would not have much affect so the analysis
for Class A would apply. As the cut-off period increases the behaviour
will diverge more and more from that of the Class A amplifier.

Simulations produce some interesting results:

Another way of measuring the source impedance is to observe the effect
on a reflected wave entering the amplifier from the load. With a Class
C amplifier, simulation reveals that the effect on the reflected wave
depends on the phase of that wave with respect to the drive signal
applied to the tube. As the phase of the reflected wave is changed,
the reflection co-efficient experienced by the wave changes. Truly a
non-linear behaviour. Intriguingly, when the conduction angle is exactly
180 degrees, this effect largely disappears, and the result is much as
if the source impedance of the tube was 2 times Rp, which seems to
make some sense since the tube is only conducting one-half of the time.

> One last question: Are you basing your dissatisfaction of Reflections

> can send you a copy of the addition.

I have been reading the .pdfs at w2du.com along with correspondence and
other writings in QST, QEX and newsgroups.

The expanded Chapter 19 at w2du.com offers more experimental evidence
that seems to support the hypothesis that the transmitter is conjugate
matched to the load after tuning,

But given, from circuit analysis, that the output impedance can not be
well defined for any but a Class A amplifier, the fascinating question
is why is there experimental evidence that agrees with the premise that
the output impedance of a tuned transmitter is the conjugate match of
the load?

One simple example to consider which has similar behaviour is a bench
power supply that also has a constant current limiter. Set such a power
supply to produce a voltage of 100V (more precisely a maximum voltage)
and a current limit of 2A. Apply a variable load. Maximum power will
be drawn when the load resistance is 50 ohms. Varying the resistance
on either side of 50 ohms will reduce the power which might be
misconstrued to suggest that the power supply has an output impedance
of 50 ohms, when, in fact, it has a infinite output impedance when
the load is below 50 ohms and a zero output impedance when the load
is above.

I have looked for such a simple explanation in the circuits of the
transmitters used in the experiments but was not able to find one.
So I am still puzzled by the observations.

After one thinks about it for awhile, one will realize that believing
in anything except physical particles is the religious faith-based
part. Can anything exist in the real world that doesn't have a
physical existence? The answer to that question is why particle
physics has become the accepted standard. Everyone who believes that
something can exist without an associated physical particle is free to
try to prove their belief but how can non-particles be measured?

You have gone to a bit higher level than I intended with my question
and
I agree with you conclusions at that level. But my question was more
basic.

When designing the filter for a PA, among other things, one uses the
desired load to be applied to the tube and the disired load impedance
to be supported and selects filter components to perform the desired
transformation.

When operating the radio, the operator has meters that measure some values, some knobs that control some component values and a procedure for adjusting these knobs.

It is not at all obvious what exactly the result of performing the procedure is. Does it result in the same load being applied to the tube that was computed by the designer? There are some hints that the procedure will result in the load applied to the tube being real, but beyond that, what exactly are the circuit conditions that result?

Since anything except a class-A amplifier is non-linear and since we are talking about linear analysis, it seems we need to locate a point in the system where V is a sine wave, I is a sine wave, and V/I is the constant impedance at that point. IMO, that is the first point at which we can use a linear math analysis and maybe that point is what Walt is talking about. It's certainly not going to be the plate of a class-C amplifier and it may not even be the load-line of the class-C amplifier. There is probably some point in an otherwise non-linear system where a linear analysis becomes possible. I think that point is what Walt considers to be the linear source point, wherever that point might be located.

In fact, here is my personal take on the subject. Given an antenna system that presents 50+j0 ohms looking into 50 ohm coax, the internal impedance of the source doesn't matter. For any voltage source, irrespective of the source impedance, if reflected energy doesn't reach the source, the source impedance doesn't matter (except for efficiency). Seems to me, the highest efficiency would be achieved by a source with zero ohms of source impedance.

Hi Keith,

By and large, Yes.

>There are some hints that
>the procedure will result in the load applied to the tube being
>real, but beyond that, what exactly are the circuit conditions
>that result?

I am a little lost on that. The load applied is the load applied
(sorry for the Zen). If you mean that the load is transformed by
tuning to a real R for the Plate to see, then, yes, that is operative.

However, that is not the end of it. That R is seen as the loss of a
now-poorer Q for the Plate tank. This is the distinction between
loaded and unloaded Q. The Plate tank Q expressed in terms of loaded
Q, to be effective, is quite low in comparison to its unloaded value.
This value of loaded Q is roughly between 10 and 20 where the
components in isolation (unloaded) could easily achieve 10 to 30 times
that.

The term "loaded" includes BOTH the plate and the applied load
(whatever is presented to the antenna connection). The only time the
unloaded Q of the Plate tank is at peak value is when it is sitting in
isolation from the chassis, circuitry, and even mounts - which means
it is not very useful in that configuration, except as a trophy. Many
silver plate their tanks as trophies (because this rarely results in
better operation).

Now, let's return to my statement about what Q is "effective" AND that
it measures out at roughly 10 to 20. This is straight out of Terman
if you need a citation. As for explanation (also found in Terman),
you have to consider that the Plate tank is the gate-keeper (as well
as transformer of Z) of power. If you have too high a Q, the power is
not getting THROUGH the tank as it must, and necessarily it remains in
the tank (as energy, albeit).

Consider further that ALL resonant circuits can be cast from series
circuits to parallel circuits or parallel to series (a fact lost on
some inventors of antennas). To describe the Plate tank in series

terms as I do, then the plate resistance and load resistance combine in series through a simple circular path through ground. There are parallel tank designs where the resistances combine in parallel. The net result is the same insofar as Q is concerned.

Consult Terman if that is confusing. No doubt others will either more clearly cite him, or add to the confusion.

Hi Keith,

Consult Terman. That should be sufficient for both the instructor and
the student to use as a benchmark design for tubes, at least. The
design of the transistorized finals' deck of Ham grade HF rigs has
been stable for nearly 4 decades.

Any departure from HF Ham grade equipment capable of 100W is going to
lead to equivocal statements.

Hi Richard:

As I understand => "output impedance of a rig be near to 50+j0" it is
not a cuantitative fact except when it refers to specific study
objects, obvously not all study objects (transmitters) will
necessarily share those numbers.
I think a good general cuantitative assertion would be for example,
"all the rig on the market gives near 50 +j0, Zout". I am not deny
that experimental fact...

When I say "in my opinion" I am just not giving a formal hipothesis or
theory and I quite understand technical and logical limitations of
such words (for that I use them)
Certainly I am definiteley not an authoritative guy on any
matter :>(

(I'm so sorry Richard, although theory of knowledge is a topic of my
interest I am not in conditions of discussing about it in a (for me)
foreign language :>( )

I saw some of this topics discussed time ago in this newsgroup and it
was not my intention to return to them because I know they motivated
good ponderings and respectfully points of view in its moment.

PSE, with the due respect and consideration toward you an the
distinguished colleagues and friends, Would you mind return to the
original question? (sorry if it is not this the most polite form to
ask it)

Yes, standing waves are hard to visualize, but there is indeed same-cycle interference involving forward waves and reflected waves. There is a certain delay from the source signal to the load and back that can be calculated if one chooses. The wave reflection model is closer to Maxwell's equations than is the lumped-circuit model where EM waves propagate instantaneously. Maybe the concepts presented in the following paper would help. There is no transmission line for a Tesla coil but reflection effects still exist. The lumped circuit model, to which you allude, incorrectly assumes that signals can travel at faster than the speed of light, an obvious impossibility.

http://www.ttr.com/corum/index.htm

Incidentally, this is the reason that W8JI measured a 3 ns delay through a foot-long 75m loading coil. There were same-cycle reflections existing in a near-infinite SWR situation. In such a configuration, the phase of the current doesn't change at all yet W8JI assumed the measured phase change was proportional to the delay through the coil. Nothing could be farther from the technical truth.

I BELIEVE! Hallelujah!

Personally as an engineer i am more comfortable working with the
electro-magnetic wave representation of radio or light waves because
i work with macroscopic objects and the waves and fields are easier to
work with. But many physicists prefer photonic representations
because they work more with particle interactions and it is easier to
represent the interactions at that level with feynman diagrams and
similar mechanics. but most problems can be adequately handled by
either if you apply the right methods.

That does not surprise me at all. I have gone through about 6 doctors in the last two years looking for one with enough IQ to even talk intelligently with. I now have a good one and he is from Iran and glad to be here. The others were just pill pushers or as I am heard to say "educated baboons". A PhD means nothing to me if there is no real intelligence to support it. Many of these specialists have no idea about other things and no ability to understand when I do go out of their comfort zone. Finding real intelligence in people is a continuing challenge for me. My IQ? Don't ask.
Cheers,
Bill Baka

Kind of what I meant. It seems that every year they are chasing
something, the latest being the 'Higgs' boson. The "Big Ring" in Europe
is a prime example by having counter rotating particles near the speed
of light smashing into each other at nearly twice the speed of light.
Sure there will be some odd particles coming from that but the life time
of these particles is sometimes measured in Nanoseconds, so they just
don't exist in the natural world.

I did, but that wasn't the point I was trying to make. The bell curve would just go up to the point that people with IQ's of 100 (by today's standards) would be considered sub par. I do wish that could happen since I can't deal with even average people. Sometimes I accidentally use a big word or describe in detail something they don't know and I get labeled either a show off or just plain smart ass. It is totally unintentional but is happens.

Hi Cecil. thank you very much for your answer. (I am a "fan" of your
rationale and very practical multiband open wire antenna feeding and I
do not know why it is no so popular as G5RV in my country).
....
I know a model is necessary false by definition because is only a
model (an approximation to the hipothetical "real thing"), but I do
not imagine what is the tranmission line in the source-load
combination of my idealized model circuit example. I am not capable to
judge validity of idealized circuit theory in general to this example,
neither. Please, could you tell me which would be the transmission
line Zo in my resistive divider example?

Anyway, my question is about validity of the assertion that reflected
wave -in that example- IS ABSORBED by the pad. According to my simple
calculations this hipothesis, as I see it, it does not coincide with

my early learnings.

For example, with a 2 V generator with Zs=1 ohm, Zc=4 ohms and Zo=1 ohm, Pc is 0.64 W. Then Pf =1 W (as Owen says in his article), Pr=0.36 W. Rendering Ef=1 V, and Vf=0.6V. Summing both in phase gives 1,6 V on the line-in point (same as on load point).
These are the same power and voltages values that simple resistive divider predicts. The system fulfills the Kirchoff law and all power (as we learn in circuits theory) it flows from source to load.
In the example I suggest a half wave transmission line loaded with 4 ohms it is at practical effects indistinguishable from a 4 ohms resistive load directly connected to generator. What would be the reflected power that would be dissipating in Zs (or the pad)?

This is not opposed to the conjugate mirror principle explained, neither other propositions given in the cited article. IMHO reflected power never "returns into" generators when they are active (and in steady state); reflected power it is re-reflected in conjugated match, and vectorially composed to render a load impedance to the generator when this is directly connected to the line (when there is not any matching devices inserted).
I do not suggesting that reflected power is "virtual" or any similar thing, of course if we insert a circulator to separate both powers, generator now would see 1 ohm load, could develope 1 W incident, 0 W reflected (Pn=1W) on circulator input, 0.36 W would be outputting on the other port to render 0.64 W (Pn) to the load with 1 W Pf and 0,36 W Pr again.

If I am in error please give me your explanations.

1733. Counterpoise for NMO in plastic roof?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-05-25 03:48:09 UTC
From: artie <artie.m@gNOSPAMmail.com>
Message-ID: <240520102048098412%artie.m@gNOSPAMmail.com>
Source record: 9733

I'm going to be putting an NMO-mount dual band (144 and 440 MHz) antenna in a plastic vehicle roof.

I plan on making a counterpoise using 3 inch wide (or so) adhesive-backed metal (hvac) tape. I can do an overlapping run of close to 6 inches wide.

Question for the crowd -- any benefit/detriment for making this counterpoise as long as possible, or should I stick to odd multiples of a quarter length (at 2 meters)?

There's more room "behind" the mount point than in front of it, so I could have a quarter wave section in front of the NMO, and a 3/4 wave section behind.

I can also do a cross member, but that would be pretty much limited to a quarter wavelength per side.

Opinions?

Good luck trying to get a good electrical connection to that stuff..
I'd probably just stick to odd multiples..
You could use wires also.. In fact, just two wires 180 degrees
apart will give you a fairly omnidirectional pattern with minimal
fuss. Easier to solder too also..
You could probably use the longer radials for 70cm, but you
could also add shorter radials for that band if needed.
BTW, another thing about that tape.. After a few months of
summer heat pounding the roof, the glue will become useless and
it will fall down on you. :/

Cecil Moore, W5DXP wrote:
"Seems to me, the highest efficiency would be achieved by a source with zero source impedance."

Me too, but zero source impedance does not match the load as required for maximum power transfer. The best combination is then a source impedance matching the load and which is also pracrically lossless. The Class C amplifier does this by acting as a switch which is infinite in impedance when open during a large part of the RF cycle and a near short circuit to a low impedance (near zero Z) D.C. power source for the short part of the RF cycle it is switched on. It is the time averaged impedance which counts. Is this linear? No way, but the tank circuit is able to remove the harmonics and turn current pulses into a low distortion sine wave. Efficiency? Terman says on page 450 of his 1955 opus that Class C eddiciency is typically 60% to 80%. Compare that with 50% efficiency in a Class A amplifier.

Best regards, Richard Harrison, KB5WZI

Well Owen...I have just read your article ¡and you have put me
definitively in a problem! :>)
I was never happened to question the Walter's work, I made effort in
learning it being a young student. Now you have put me in a corner and
I will must meditate hard about the issue (with your help,
certainly).

In principle I take a risk to think that somehow it is necessary to
solve "what to do with the reflected traveling wave" because the model
seems to demand "come off of her" somehow that it doesn't return into
the generator, and an explanatory model (and IMHO appropriate) of
making it is to postulate its re-reflection to be consistent with it.

In conventional theory of circuits we simply apply the second law of
Kirchoff because we do not have traveling waves and we accept that the
energy can only flow from the generator toward the load (supposing a
circuit without reactances), there is not anything to come off (in
spanish => deshacerse, desprenderse) :>)

I am happened to think that your article combine concepts of both
models, those of basic circuit theory (without traveling waves) and
those of the traveling waves -same as my simple example of course-

with the difference that in mine one I only wanted to point that the reflected power is not "absorbed" by the pad, and yours is critic of conjugate mirror model and other postulations.

I think the mixture or combination of models -maybe- it would not be "elegant" or consistent although it can arrive to the same numerical results, but I don not dare to advance more than that in my speculations :>)

>
>>ï¿½Absorb the reflected power or amortiguate the effects of variyng load
>>impedance?

The answer is YES.

Now, if you mean by absorb that all absorbtion results in heat, then
the answer is NO.

If you mean by absorb that all energy is combined in a load, then the
answer is YES.

The difference between YES and NO is the PHASE differences of the two
energies that are combined.

Miguel,

My explanation uses standard linear circuit theory, and the RLGC model of a transmission line (captured in the Telegrapher's equation). It is a frequency domain model, and it is complete and consistent.

One of the things that creates confusion in some peoples minds is that they want one foot in the frequency domain (where you can talk about concepts like reactance, complex impedance, VSWR) and simultaneously, one in the time domain taking about re-re-reflected waves.

You can work in either domain, and you can transform between domains, but trying to be in both at the same time creates problems.

BTW, if you think the problem is challenging to solve in the frequency domain, don't even think about trying to solve it in the time domain.

So, do not worry about re-reflection, it is dealt with as you have discovered by the steady state solution when you load the source with the (steady state) impedance seen looking into the line. The resolution of the wave component voltages and currents with KVL and KCL at the circuit nodes gives the steady state solution. The Telegrapher's equation gives you the amplitude and phase relationship of the wave components for the transmission line, not just for fictitious lossless lines, but for practical lines as the example demonstrates.

A steady state frequency domain analysis is quite adequate for most ham problems. You don't see it spelled out as such, but that is how the ham handbooks describe and solve problems.

As far as the myths about PAs destroyed by absorbing reflected power, see "Does SWR damage HF ham transmitters?" at http://vk1od.net/blog/?p=1081 .

Hi Richard and Owen

To Richard: What I mean is irrelevant :>) relevant is what Walt wanted to say in this sentence: "Because of the absorption of the pad, the generator sees a nearly perfect match for all load conditions and all reflected power is lost "
Pllease, tell me what in english means "all reflected power is lost"? I understood (or translate or interpret) that reflected power is dissipated in the pad: Is it a bad translation/interpretation?

To Owen: Sincerely thanks for your reasons. You can be sure I will take note about your explanation an take some time tu analize it, but I am not sure about to arrive at at the right conclusion because what I read in this newsgroup is a long-standing discussion here.

Miguel

Another bit of reading that might help shed light on the matter is http://eznec.com/misc/Food_for_thought.pdf, written eight years ago during one of the many times the subject has come up before on this newsgroup.

The chart and discussion in the "Forward and reverse power" section show that the concept of "reflected power" being absorbed in or dissipated by the source is incorrect. I find the concept of traveling waves of average power to be misleading at best, and analyses using this concept lead to impossible conclusions like the supposed absorption of power in the source resistance.

Yes, it is a recurrent discussion item. No doubt someone will be along shortly to add some confusion to the pot.

A parting thought, do not confuse the process of establishment of steady state with steady state. The only reason that a steady state solution is valid, is that the system spends most of its time in steady state, or substantially so. If the solution needs to focus mainly on establishment of steady state (in other words, the system never substantially settles), then you should be doing a time domain solution, and VSWR, reactance, complex impedance are not a time domain concepts.

If you need to convince yourself, do a hand workup of five of ten transits with a sinusoidal excitation. See that is does converge, and quickly, and that at the load end, the reflected wave relative to the forward wave is a fixed ratio (and hence VSWR) that depends ONLY on Zo and Zl, there is NO influence by the source or any perceived source reflection on the steady state. There are some animations of this on the net, but they seem to confuse people more than enlighten them.

In optics the light is in form of packets (oscillations for short time and
next brake - of course there are many sources).

>how could he see it since the equipment was set up to radiate into a
>detector. It may not be in our lifetimes that the true nature of light is

Why?
If we can produce the artificial light (LEDs, laser) and we know that radio
waves are the same then we know all.
Radio waves are very convinient to analise.
They are the longitudinal electric waves which propagate in the electron
see.
It is very old theory. The only trouble was with the polarization. But now
radio people know that the dipole is polarised. In nature all light sources
are in form of dipoles.

Well, for the purposes of application of linear circuit theory,
linearity means that V is linearly related to I, or at least dV/dI over
the operating range is substantially constant.

If the circuit is not linear in those terms, then you cannot form a
valid Thevenin equivalent circuit, and discussion of the Thevenin
equivalent series source impedance is a nonsense... it cannot be used.

In one wavelength but still in packets.

But now are the fantastic lasers with the infinity "packet". Exactly like
radio waves:
""As the electrons are undergoing acceleration they radiate electromagnetic
energy in their flight direction, and as they interact with the light

already emitted, photons along its line are emitted in phase, resulting in a "laser-like" monocromatic and coherent beam. The mirrors show in the sketch below are superfluous, as all the light is emitted in one direction anyway." From: http://en.wikipedia.org/wiki/Halbach_array

One thing: the MTM loop antenna doesn't need a connection to the AM
radio. That web-page, if I read it correctly, said you only needed to
put the radio next to the loop antenna.

Recalling that if a conjugate match is achieved at one ponit in a
system
it is achieved at all points....

It does not seem possible for a system to be non-linear at one end and
turn in to a linear system at some other point.

True, if the source impedance originates in dissipative components and
it is a voltage source. For a current source, infinite impedance
offers
the best efficiency.

It seems to me that much too much is made of 'maximum power transfer'
in
the RF world. In the world of 50 and 60 Hz, where significantly more
energy is moved, 'maximum power transfer' is never mentioned.
Efficiency
is much more of interest.

For the most part, 'maximum power transfer' is just an interesting
ideosyncracy of linear circuit theory.

A 60 Hz Power Generation Plant operates at high efficiency, not at the
maximum power transfer point. If they were 50% efficient, they would
go out of business. (That's what Edison expected.) Why is maximum
power transfer desirable in ham transmitters? Is such a design the
highest power/cost ratio? Is it possible to build an output amp with a
10 ohm source impedance designed to be 80% efficient? 1 ohm source
impedance designed to be 98% efficient? Is co$t the driving parameter?

That will work if that's what you want to do. The radio's ferrite
antenna replaces the 2 turn pickup loop. If you want to be able to do
both, include the pickup loop anyway.

Good luck!

Well, consider the following two systems. Z01 is 50 ohms and Z02 is 300 ohms. The two systems are identical except for the circuits hidden inside the two identical source black boxes. Both sources are supplying a 100v sine wave to the system.

Source1----Z01----+----1/4WL Z02----1800 ohm

Source2----Z01----+----1/4WL Z02----1800 ohm

Every passive voltage, current, power, and impedance measurement is identical in both systems. As far as we can passively measure, both systems are identical and linear. The only thing we don't know is what is inside the two source boxes..

Inside the Source1 box is a linear ideal 50 ohm Thevenin equivalent source delivering an ideal 100v sine wave. Inside the Source2 box is a non-linear class-C amplifier filtered to provide an ideal 100v sine wave.

Without changing the system conditions, can one make a passive measurement to determine which system is conjugately matched and which one is not conjugately matched? If one cannot tell the difference, are they both conjugately matched, or both not conjugately matched, or what?

Here's my take. A 50 ohm Z0-match exists in both systems and all conditions are identical on the load side of that Z0-match. In particular, at any point in the system on the load side of the Z0-match, the impedance looking in one direction is the conjugate of the impedance looking in the other direction. That is a characteristic of a conjugate match. So are both systems conjugately matched between the Z0-match and the load? If it walks and quacks like a duck ...

> The chart and discussion in the "Forward and reverse power" section show
> that the concept of "reflected power" being absorbed in or dissipated by
> the source is incorrect.

I'm sorry, Roy, but that is a very misleading statement. There are
THREE things that can possibly happen to the reflected energy.

1. It can indeed, be absorbed/dissipated by the source but it
certainly doesn't have to be. The conditions governing absorption,
reflection, and redistribution of EM wave energy are well understood
in the field of optics. RF gurus seem to be myopic about interference
effects.

2. It can obey the laws of the reflection model for EM waves, e.g. if
the source impedance is different from the Z0 of the transmission
line, some reflected energy will be re-reflected. (I know that doesn't
apply to your "food for thought" examples because the source resistor
is equal to the Z0 of the feedline.)

3. The interference phenomenon that you completely ignored in your
discussion, presumably through ignorance. This third possibility for
the reflected energy redistribution is associated with constructive
and destructive interference. It is the same phenomenon that is in
operation with the 1/4WL coating on non-reflective glass. Here's a
quote from a Florida State University web page with capitals added by
me for emphasis:

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/
waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are 180-
degrees ... out of phase with each other meet, they are not actually
annihilated, ... ALL OF THE PHOTON ENERGY present in these waves must
somehow be recovered or REDISTRIBUTED IN A NEW DIRECTION, according to
the law of energy conservation ... Instead, upon meeting, the photons
are REDISTRIBUTED TO REGIONS THAT PERMIT CONSTRUCTIVE INTERFERENCE, so
the effect should be considered as a REDISTRIBUTION OF light (and RF)
waves and PHOTON ENERGY rather than the spontaneous construction or
destruction of light."

This is the concept that you have been missing for eight years.
"Redistribution of energy" in a transmission line is simply a reversal
of energy flow. Each of your examples have different magnitudes of
interference (depending on the phasing between the forward energy and
the reflected energy). The phasing is a variable for all of your

examples. Why did you completely ignore the interference? Why would you expect a CONSTANT magnitude of reflected energy to be dissipated in examples with VARIABLE phasing and VARIABLE levels of interference??? Here are the possibilities:

1. No Interference at the source resistor - this happens when the forward wave is 90 degrees out of phase with the reflected wave at the source resistor. In this case, the reflected energy is indeed dissipated in the source resistor. I have written a short article on the no interference case at:

http://www.w5dxp.com/nointfr.htm

2. Constructive Interference at the source resistor - This happens when the phase angle between the forward wave and reflected wave is less than 90 degrees at the source resistor. The voltage across the source resistor increases and therefore more power is dissipated in the source resistor. In fact, for total constructive interference, all of the forward power and all of the reflected power is dissipated in the source resistor. This happens when the SWR is infinite and the reflected wave arrives at the source resistor in phase with the forward wave from the source.

3. Destructive interference at the source resistor - This happens when the angle between the forward wave and reflected wave is between 90+ degrees and 180 degrees. In this case, reflected energy is redistributed back toward the load and less is dissipated in the source resistor. In fact, for total destructive interference, zero reflected power is dissipated in the source resistor and all of the reflected energy is redistributed back toward the load. This happens when the SWR is infinite and the reflected wave arrives at the source resistor 180 degrees out of phase with the forward wave from the source.

I explained all of this in my "WorldRadio" article way back in 2005. Presumably, you have never read it. In order to understand the role that interference plays during the superposition of EM waves, you might want to read it and take a look at the references. The question of where reflected energy goes was answered long ago by optical physicists. Too bad that RF gurus remain so ignorant of that knowledge. Here's that five year old "WorldRadio" article.

http://www.w5dxp.com/energy.htm

You obviously know how to add voltage phasors but you are obviously ignorant as to what happens to the ExH power in each of those waves. In any optics reference book, you will find the following irradiance equation. Since irradiance uses the same units as the Poynting vector, I have changed I (irradiance) to P (power density) in the irradiance equation. I first saw this equation in Dr. Best's QEX article[1].

Ptot = P1 + P2 + 2*SQRT(P1*P2)cos(theta)

When any two EM waves are superposed, whether light waves or RF waves, this is what happens to the component powers. The phase angle, theta, is the relative phase angle between the two electric fields before superposition. The last term in the equation is called the "interference term" and it is easy to see how it modifies the total power in the wave after superposition. Energy must be conserved. If destructive interference occurs between two waves in a transmission line, constructive interference must occur in the opposite direction - and vice versa.

By completely ignoring the destructive and constructive interference occurring in your "food for thought" examples, you have ignored the accepted laws of physics (available in any physics optics reference) and arrived at completely false conclusions. Roy, every one of your examples can be explained simply by using the above equation from the field of EM wave optics. Differing types/levels of interference explains every one of your examples perfectly.

Miguel, let's switch your example over to an easier to understand example. Assume an ideal signal generator equipped with a resistive circulator load. Let's call such a device an SGCR, a Signal Generator equipped with a Circulator and a Resistor. Assume that 100% of the reflected energy is dissipated in the circulator load resistor (none re-reflected) and none of the reflected energy reaches the source. So here is the block diagram.

SGCR--------feedline--------load

That model should be easier to discuss than the pad attenuator model. What do you think?

Hi Miguel,

Your translation is fine.

However, I have no idea what the pad design looks like, nor do I know the component values. I have calibrated thousands of standard pads at frequencies up to the 12 GHz. They came in either a Pi design, or a T design. Their intended use is in system isolation. That is, they isolate the source from the load OR isolate the load from the source OR isolate both. For certain component values, you can replace the "OR" with "AND."

You would isolate the source to keep its frequency and power constant. You would isolate the load to keep line SWR flat. For this line application, it is assumed you are calibrating either a load equal or nearly equal to Zc, or you are measuring RF power. These are the purpose of pads (they also serve the same function in audio circuits). Measuring power in the presence of SWR other than 1:1 requires sophisticated math that is rarely discussed here. Most discussion usually accepts the presumptions of special cases (which are often sufficient) and employ less rigorous formulas (which serve well within the unstated presumptions).

In conventional Kirchoff analysis, the resistor that bridges the transmission line opening becomes the source (that is Vs and Rs). Pad design usually makes that one resistor for the Pi pad, or two resistors for the T pad. If you are working in accurate and precise measurement, you then account for the input (source) resistance in parallel/series combinations. This second computation is the numeric analysis of isolation. The higher the ratios of these pad resistors, the higher the isolation.

It doesn't normally serve any use to have the pad apparent resistance (what I called Rs above) different from Zc or from Zload, but as this component is a sacrificial one, the designer may choose to put it to

use to achieve a desired goal. Pad performance suffers with heat due to energy combinations that come from multiple/single sources.

>equivalent series source impedance is a nonsense... it cannot be used.

The counter argument, as I understand it, is that the tank circuit isolates the linear from the non-linear, and that the tank also performs the action of transformation. Thus the proposal is an analysis of their combination (I had to struggle to avoid superposition).

Thus, the non-linear Tube (because, I presume, the circuit is in Class C operation) exhibits a higher efficiency than would be found in a resistance matched system. What I call the resistance matched system is the unfortunate appeal to a source "resistance" equaling the load "resistance." Thevenin/Norton do not mandate resistors, rather impedances.

What I understand, comes from lengthy emails with multiple contributors in years past: Walt and Richard being two of them. My saved mail only goes back nine years, so the other two contributors' names are lost to me right now.

Of course what I "understand" may be wholly misrepresented by my exposition here. So be it. The source authorities can correct my deviations.

by definition, an IQ of 100 *is* the median, and the standard deviation is 15. IQ is a normalized measurement. (it hasn't been 100*mental age/chronological age for decades..)

And there's a radio connection here.. Lewis Terman, who invented the Stanford-Binet IQ scale was the father of Frederick Terman, of EE fame.. both were at Stanford. And Bracewell (another EE) held the Lewis Terman professorship

Hi there,
I have had some experience with BCB boosters and found that it works best with a long wire coupled to a loop that is grounded. The radio I was using had a built in antenna wound inside the case and the untuned loop coupled very nicely to the radio. With a ferrite rod inside the radio it might not work so well.
Just an idea for you to play with.

Hello Keith,

Thank you for your response. I'm starting my answer to your statements by first quoting from one of your posts:

"Try as I might, I have not been able to derive a mechanism to explain the observations in Reflections. But the explanations offered in Reflections require large chunks of linear circuit theory to be discarded, so this does not seem to be an appropriate path."

That you have been unable to derive a mechanism that explains the action in an RF power amplifier is evidence that you do not understand it. So let's examine the action that follows an appropriate path that does not require any linear circuitry to be discarded. Further evidence that you do not understand it is that you used a bench power supply to describe the action, which you state has an infinite source resistance when the load exceeds 50 ohm, and zero source resistance when the load is less than 50 ohms. Unfortunately, this power supply in no way resembles an RF power amplifier, either in components or action.

We'll begin by stipulating that the 'filter' is a pi-network tank circuit, having a tuning capacitor at the input and a loading-adjustment capacitor at the output. We'll also stipulate that the plate voltage and the grid bias are set to provide the desired conditions at the input of the tank circuit, which means that the desired grid voltage is that which results in the desired conduction time for the applied plate voltage. The result provides a dynamic resistance RL, which is determined by the average plate voltage VPavg and the average plate current IPavg appearing at the terminals leading to the input of the tank circuit. In other words, RL = VPavg/IPavg. To permit delivery of all available power to be delivered by the dynamic resistance RL, we want the input impedance appearing at the input of the tank circuit to be equal to RL.

We'll now go to the output of the tank circuit. We'll assume the load to be the input of a transmission line on which there are reflections. The result is that the input to the line contains a real component R and a reactance jX. The output terminals of the tank circuit are the two terminals of the output-loading capacitor. When the line is connected to the output terminals of the tank circuit the reactance appearing at the line input is reflected into the tank circuit. This reactance is then cancelled by the tuning capacitor at the input of the tank circuit, resulting in a resonant tank circuit. We now need to adjust the output-loading capacitor to apply the correct voltage across the input of the transmission line so that the real component R

appearing at the line input is reflected into the tank circuit such that the resistance RL appears at the input of the tank circuit, thus allowing all the available power to enter the tank circuit. In other words, adjusting the loading capacitor to deliver all the available power into the line also makes the output resistance of the tank circuit equal to the real component R appearing at the line input. With any other value of output resistance of the source, all the available power would not be delivered to the line. A corollary to that condition follows from the Maximum Power Transfer Theorem that for a given output resistance of the source (the tank circuit), if the load resistance is either increased for decreased from the value of the source resistance, the delivery of power will decrease. This condition also accurately describes the condition for the conjugate match.
Keep in mind that the input impedance of the line is complex, or reactive, but the reactance of the correctly-adjusted tuning capacitor has introduced the correct amount of the opposite reactance to cancel the reactance appearing at the line input. Thus the line input impedance is R + jX and the output impedance of the source is R − jX, providing the conjugate match.

You stated in one of your posts that the phase of the reflected wave in relation to that of the source wave results in a non-linear condition. This is totally untrue. The tuning action of the input capacitor in the tank circuit that cancels the line reactance caused by the reflection on the line in no way introduces any non-linearity in the circuit, and the condition in the vicinity of the output of the tank circuit is totally linear. Thus, circuit theorems that require linearity to be valid are completely valid when used with the RF power amplifier as described above. This applies to all RF power amplifiers, Class A, AB, B and C.

I hope my comments above assist in understanding the action that occurs in RF power amplifiers.

Sort of.
Start with two parents who are above 140 and encourage them to have kids and educate them starting at day one. It would obviously offend the Vatican, but religious beliefs are fantasy anyway. Just discourage people with low IQ's so they won't breed like rabbits. It could/would work if people weren't so hung up about their right to have children. That show on TV, 19 and counting makes me sick. People like that are a major cause of de-evolution.

Hi Bill,

It is on at least twice during the weekend on NPR (I don't think
anyone else, commercial radio, has ever carried A Prairie Home
Companion). Robert Altman made it into a movie 4 years ago.

NPR is usually found in the public service (think campus stations) end
of the FM band.

Roy's notes lead you into thinking about instantaneous power, and the behaviour over a complete AC power cycle. Thinking that through, and the implication about the power/time graphs at various points on the transmission line gives insight into average energy flow, and energy exchange between line sections, line and load and line and source, and the physical bounds of exchange of stored energy during a cycle.

The Telegraphers Equation that I mentioned earlier captures the behaviour of the line, and basic AC circuit theory, Joule's law etc takes you the rest of the way.

Sure, working these things through takes time... and there isn't much afforded in today's world of instant gratification where appealing explanations are more accepted, irrespective of whether they are correct.

Miguel, invest in yourself and your knowledge, don't accept explanations because of a vote count, accept them because they reconcile with things that you truly know as facts (which sometimes means challenging what you think you know).

Methinks you have so constrained the experiment as to make it
unsolvable.
But let us test that.

Consider a Source3, much like Source1: linear, ideal, but 100 ohms
output impedance. It is connected to the same load you specify for

Source1 and Source2 and adjusted to drive 100 volts in to the 50 ohm Z01 line.

You are presented with the circuits using Source1 and Source3.

We know that Source1 and Source3 can not both be conjugately matched.

"Without changing the system conditions, can one make a passive measurement to determine which system is conjugately matched and which one is not conjugately matched? If one cannot tell the difference, are they both conjugately matched, or both not conjugately matched, or what?"

Some people just don't like the show. Even those of us that live nearly
next door to the clod that makes the it. No offense, but he is not nice
a nice guy and is quite offensive to the local population.

Not kidding.

Dear friends

Sincerely it was not my desire to vivify old polemics but to tell the truth, eight years it is a lot of time for not having arrived to a consent!; hey boys this is science non religion! We must have a way of leaving the well! :>)

Is not possible you are using different models to describe an only one phenomenon?, as looking at the same cat from their muzzle or from his tail believing each one his cat is the true or real "cat" :>)

I finished reading Cecil's article (http://www.w5dxp.com/nointfr.htm) and I took of his example that of the 12,5 ohm load. I took a Smith's chart and obtained the line input impedance, then I applied basic circuits theory and I obtained the same value of power dissipated in Rs -exactly-
As I see, if we use a simple electric model of generators and impedances to solve the problem (maybe like Owen suggests), we can explain the dissipation in Rs without appealing to any reflected power returning into the generator because the interference phenomenon that Cecil describes takes place to form the impedance that generator see.
Or alternatingly the dissipation can be described by means of the equations that Cecil shows in its page. In such case we should consider both powers (direct and reflected) operating simultaneously on generator resistance. Same cat, different points of view... :>)

Perhaps my vision is naive but this situation reminds me an example of Sears and Semansky book "University physics" (third edition) where he explains that energy can be thought as not transported by charges in movement, but for the electromagnetic field associated to them. Last is a little hard to see -Poynting vector et al- :>) but it is applicable.

Always has been a pleasure for me to read you. I have learneing very much from your enthusiastic discussions. You made me think of things that I never thought without your help. Thank you.

Miguel Ghezzi . LU6ETJ

PS: Meanwhile I take the Owen advice and I am still studying!

Hi Miguel,

You got on this train rather late if all you see is eight years of it.
The circular references have entertainment value - so did vaudeville.

I do admit reading way too much, but I enjoy the professional Magazines
I get in the mail. My reading habits go far beyond just electronics and
compute so I read Military and aerospace, NASA tech briefs, information
week, EDN, Electronics design, and many more. I can at least push my
brain as hard as possible.
BTW, does anyone here know a good grammar checking program.
There are some good windows 7 products but my scanner will not let me
use it in Linux land since h.P. has flat out told me my 4 year old
scanner is now obsolete and they are making new scanners, won't even
attempt to fix the driver mode since H.P. never made any drivers for Linux.
Come summer, if it ever gets here, I will be busy on my 100+ mile
bicycle rides. These take from sunup to sun down, but burn huge amount
of calories climbing endless hills.
Return to school? I might take classes at the local junior college and
collect about three or four subjects and try to get 4 or 5 Associate

degrees. I won't be able to that and actually finish with requirements that are needed (forced down my throat) So that would be a logical start for me. Cal state in Sacramento is the next college for the next four years, but I can challenge some of them.
It is an idea but for the summer I am going into physical fitness and not computer mode. It may be a little 'old' at my age but I can do the school work just as easily as ever.
Cheers,
Bill Baka

No excuse, just too far down on the income to actually join one.
My brain is in no position to pay for a membership and and I would not
want to take an IQ test after a night of no sleep. If I qualify for Giga
society I would be amazed. I might just luck out and qualify, but who
knows? I am not intentionally doing anything to average people but some
times I over-estimate people's ability to understand.

I'm not into the bragging mode and never had to be. Of course I put down some fellow engineers at one job. All I know is that I can take a look at almost anything and make it better.

"No way" is a bit strong. The RF PA is constructed from a constant
voltage source (the power supply) and a constant current controller
(the tube), both aspects present in the bench supply example
previously
offered. A tube is often modelled as an ideal variable constant
current
source but unlike an ideal source, which can produce whatever voltage
is needed to drive the current, the current produced by the tube is
limited by the power supply voltage. Thus, assertions of linear
behaviour need to be tempered by ensuring that such voltage limits
are not exceeded.

Most references use Vpeak and Ipeak, though they are usually related
to average values with constants of proportionality so the computed
RL will be the same. None-the-less, I prefer peak values since it
ties better to the choices made in the design.

The power that can be controlled by a control device (be it a switch,
tube or transistor) is related to device limitations. So, for example,
the maximum power that can be controlled by a 250V 1A switch is 250W.
This occurs with a supply voltage of 250V and a load of 250 ohms.
Increasing the supply voltage exceeds the switch capability as does
reducing the load resistance.

If the supply voltage is less than 250V then the maximum power occurs
with a load that causes 1A to flow and is now a limit based on
circuit choices and device capabilities.

Note that these power limits have nothing to do with maximum power
transfer in a linear circuit.

Similarly in a tube circuit, the maximum power is limited by the
supply
voltage and the tube drive level (which sets the current that will
flow in the tube). Maximum controlled power is then V*I and occurs
with a load resistance of V/I. Increasing the load resistance reduces
the power because there is insufficient voltage from the supply to
drive more current through the load and reducing the load resistance
reduces the power because less voltage is impressed across the load.

Note that neither of these effects is related to the maximum power
transfer in a linear circuit.

While a conjugate match does result in a situation where altering
the load will reduce the power transfer, it is not true that any
situation where altering the load reduces the power transfer is
also a conjugate match. The two examples above (bench power supply,
tube in a circuit) amply demonstrate this.

This is quite in error, unless, by happenstance, RL is equal to Rp
(plus
the other contributors to source impedance).

> amplifier as described above. This applies to all RF power amplifiers,
> Class A, AB, B and C.

For any circuit with a conduction angle of less than 360 degrees, my
simulations indicate otherwise. The reflection coefficient experienced
by the reflected wave when it arrives at the amplifier output varies
with the phase of the reflected wave. Since the reflection coefficient
is a function of source impedance and line impedance, and the line
impedance is not changing, this means that the source impedance is
changing with the phase of the reflected wave. This is not a behaviour
that is consistent with a linear circuit. Given the non-linearities
in a circuit with a conduction angle of less than 360 degrees, this
should not be a surprise. More, it would be a surprise if such a
circuit did behave as a linear circuit.

> I hope my comments above assist in understanding the action that
> occurs in RF power amplifiers.

Thank you. They have indeed helped clarify my thinking.

We are still left with the puzzle of why the observations documented in Reflections report a reduction in power transfer when the load is changed in either direction. It seems unlikely that RL is, by happenstance, equal to Rp, which would be one explanation.

It seems plausible that it is related to the behaviours associated with the examples I provided above, but I can not articulate a mechanism that satisfies.

…Keith

Sorry, what that means is all you need to do is place the radio near the loop, just like you mentioned earlier. If you want to connect to output of the loop to the antenna input of an AM receiver at some later time, that will work, too. If you don't think you'll use the output from the pickup loop, then skip it for now. You can always add it later if you need it.

Good luck.

Dr. Corum tells us what the problem is: "Lumped circuit theory fails because it's a *theory* whose presuppositions are inadequate. Every EE in the world was warned of this in their first sophomore circuits course. ... The engineer must either use Maxwell's equations or distributed elements to model reality. ... Distributed theory encompasses lumped circuits and always applies."

In particular, *energy flow* is not addressed at all in the lumped circuit model. Some RF gurus are so confused that they imply that there is no Poynting vector power density in reflected waves. Their basic error (for the past 8 years) is that they believe there is no mechanism outside of the reflection model that can redistribute the reflected energy. But what can happen to reflected energy has been known for decades in the field of optical physics. The reflection that one sees in a mirror contains an ExH power density that activates one's human retina. Waves cannot exist without energy. Standing waves cannot exist without forward and reverse traveling waves. That some otherwise knowledgeable and influential RF gurus deny the reality of such is really sad.

What they are missing is simple. The FSU web page describes how wave cancellation redistributes the reflected energy back toward the load from what is essentially a Z0-match. The redistribution of reflected energy due to wave cancellation is technically NOT a re-reflection since it involves destructive interference between TWO waves. When the RF gurus broaden their knowledge base to include wave cancellation, they will alleviate their ignorance on how reflected energy is redistributed back toward the load. That knowledge can be obtained from any good optics reference book including "Optics", by Hecht and "Principles of Optics", by Brown and Wolf. Until those gurus admit to themselves that they are not omniscient, the argument will continue.

> I finished reading Cecil's article (http://www.w5dxp.com/nointfr.htm)

Remember that article describes the two special cases where the two superposed waves are 90 degrees apart and therefore do not interfere with each other, i.e. no wave cancellation exists. I have not yet written the other two articles about constructive and destructive interference.

I have a cheap Sony Dream Machine radio. It has no AM antenna port. SO
the loop antenna should boost its AM reception. That's why I asked. :)

Could FM reception be boosted by the same idea? That Dream Machine radio
has only a simple wire as FM antenna.

Continuing after taking my wife to work:

The reason that optical physicists know so much more about energy transfer than RF gurus is that the optical physicists do not have the luxury of measuring the voltage and current associated with an EM wave at light frequencies. They have historically been forced to deal with irradiance, i.e. power density, at every step of their analysis since that is the only thing they could easily quantize through measurements. As a result, they know everything one needs to know about where the energy goes during reflection and wave cancellation. If one wants to catch up on such as it applies to all EM waves, including RF waves, please obtain a copy of "Optics", by Hecht and read the chapters on superposition and interference. It was an eye opener for me and resulted in my WorldRadio energy analysis article.

http://www.w5dxp.com/energy.htm

Optical physicists usually make power density (irradiance) measurements and then calculate the electric and magnetic fields of the EM wave. RF gurus make voltage and current measurements and ignore energy/power except for net power in and net power out thus losing important details in the process. When they don't understand energy transfer, they dismiss it as unimportant or worse yet, assume that their ignorance somehow proves something as W7EL has done in his "food for thought" article on forward and reflected power. All that he has succeeded in proving is his ignorance of partial or total wave cancellation involving two superposed component waves which can reverse the flow of energy in a transmission line just as easily as can an actual reflection. Here is a diagram of the energy flow at a 50-ohm Z0-match as is common in ham installations.

http://www.w5dxp.com/enfig3.gif

Pref1 = Zero = P3 + P4 - 2*SQRT(P3*P4)

where P3=P4 and the two electric fields are 180 degrees out of phase. This is total destructive interference due to wave cancellation, i.e. out-of-phase superposition.

Pfor2 = P1 + P2 + 2*SQRT(P1*P2)

This total constructive interference due to in-phase superposition.

If W7EL would use the general power density equation on his "food-for-thought" examples

Ptot = P1 + P2 + 2*SQRT(P1*P2)cos(theta)

he would obtain all the correct answers as to where the reflected energy goes, i.e. the energy analysis would agree exactly with his voltage analysis. That energy analysis would tell us exactly how much reflected power is absorbed in the source resistor and exactly how much is redistributed back toward the load as part of the forward wave. But when W7EL heard these facts of physics from the field of EM wave optics many years ago, he said "Gobbleygook".

Kraus, Jasik, and Balanis might disagree - maybe even Terman.

Why are antennas a less desirable specialization than any other
specialization? Is counting the barbs on a fruit fly's penis to
determine its exact species somehow superior to antennas? :-)

Intelligence is a tool,

Talent is a tool,

But they are not the only tools in the box.

There is drive, there is curiosity, even OCD or Asperger's can be turned into a tool.

There is memory. There is personality.

I'm around 150, but all that means is that if a problem interests me, I can figure it our a little before someone who has a lower number.

Big deal. Some times I think there is something else too, but I'm too dum to put my finger on it. I've noticed that there is something of a troubleshooting skill that I've got/cultivated that often allows me to diagnose a problem a lot more quickly than most other people. Even that's not much help, because I can often figure out a problem in a minute, then spend the next 20 minutes trying to convince the other people I'm with. That's led to some interesting moments, but point is I think there is some ability to compartmentalize mental functions that isn't directly related to IQ.

A fellow who worked for me at one time had a figurative ton of talent. Awesome photographer, highly skilled at tabletop studio photography.

Unfortunately, he had no drive, and his work life was a sad cycle of his talent landing him jobs, and his lack of drive losing them for him.

I've known people with below average intelligence who had other tools like drive and personality that made them successful, and a joy to work with.

Hi Keith,

Stripping away everything that you offer as objections to what is not
in Walt's premise (I cannot vouch for his attempts to explain the
universality of it), your statements come into conflict.

If you offer you find a puzzle about measurements, then that is simply
researched at the bench instead of in expansive wanderings in myriad
qualifications. Do you have documented measurements under initial
conditions identical to Walt's that run counter to Walt's quantitative
results?

I suspect not, or we would be talking about competing bench results
instead. This would be a more productive and genuine debate seeking
explanation for what you describe as the "puzzle."

Barring quantitative evidence, anything that continues this rag-chew
is a simple example of "modeling is doomed to succeed."

It is only a number and our individual talents can be very different.
I solve a lot of abstract problems and can instantly visualize things
that can and should be improved. It really does not matter here. We were
really just comparing notes, not bragging. I'm sure some on here could
bury me, especially in antenna design. I find that my brain wants a lot
of input so I study various things even though I will never work in
those fields. I'm 61 so why go back to school??
I am a generalist, not a specialist. Curious about many things, and as
you are posting I am still learning about humans reacting to a mere
number. I came on here originally to ask if anyone knew about a noise
blanker that could be inserted into the receiver/antenna, nothing more.
I did expect that most hams are above average, but did not anticipate
any hostility. Don't be so touchy, I came here to learn and possibly
contribute some of my projects and how they turned out.

Continuing this thought thread - Assuming 50 ohm coax from the source
containing a forward traveling wave and no reflected wave, i.e. an SWR
of 1:1 on 50 ohm coax, what it to prohibit us from drawing our system
box through that piece of coax and considering the signal emerging
from that piece of coax to be the linear source signal which is
obviously associated with a V/I = 50 ohm impedance?

Hi Keith,

Sorry, OM, but you still misunderstand various aspects of RF power amp
operation.

First, the power supply is not the limiting factor concerning plate
current. The grid drive is what determines the plate current, and thus
the output power.

Second, the tank circuit is an energy storage device that isolates the non-linear input from the linear output. That the output is linear is because the voltage and current are in phase at the output of the tank circuit. The effect of the energy storage of the tank results in the tank becoming the source of the energy appearing at the output.

Third, the action of plate resistance Rp occurs only in the formation of RL, and has no further effect on any action downstream of the input of the tank circuit. Thus, it has no bearing on the development of the conjugate match that occurs at the junction of the tank output and the input of the transmission line.

Fourth, as I said earlier, the the action of the bench power supply that you presented in no way models the action of the RF power amplifier. Furthermore, you are incorrect when you say that when varying the load in either direction causing the power deliver to decrease there is no conjugate match. In saying what you did violates the theorem of Maximum Transfer of Power.

Fifth, as I stated earlier, when the reactance appearing at the input of the load (the transmission line with reflections) is canceled by the opposite reactance introduced by the pi-network tuning capacitor, the output impedance of the source (the tank circuit) is the conjugate of the line-input impedance. If you cannot accept this as fact you have a problem.

Sixth, your understanding of the effect of the reflected wave on the source wave is flawed. The non-linearity of the plate current when the conduction time is less than 360° has no relation to the action downstream of the input to the tank circuit, because from that point on the voltage current relationship is linear. If you cannot accept this as fact you have still another problem.

Seventh, your belief that because there is a conjugate match at the output of the tank there must be a conjugate match at the input of the tank is also not true. The effect of the energy storage in the tank isolates the non-linearity af the input from the linear operation at the output, permitting a conjugate match at the output, while not allowing it to occur at the input.

These seven comments are born out (proven) by the results of many measurements I made using laboratory grade instruments, HP and General Radio. If you check my record as a professional electrical engineer regarding the measurements I've made that led to successful hardware flying on various Earth-orbiting platforms, you must accept the validity of the measurements I made on RF power amplifiers that prove my position.

As I said earlier, no one but you has considered my position on this subject incorrect. Therefore, if you cannot agree with the comments I made above, but still consider my statements in Reflections flawed, then there is no point in my making any further comments. I hope someday you'll finally understand what's really happening within the

RF amplifier.

Cecil, have forgotten that because the source resistance of the RF
power amp is non-dissipative, none of the reflected power is absorbed
therein?

Actually, this discussion is based on an example introduced by W7EL
which assumed a 50 ohm source resistor in his "food for thought,
forward and reflected power" article posted on his web page. The
source resistance of an actual RF power amp doesn't matter. W7EL's
example specified a 50 ohm resistor as the source impedance.

Thanks but my last balun was tossed in the Atlantic Ocean in 1979 and I
will never (ever) use another one. Bill, W9INN, used a center connector
that looked like the W2AU balun in in antennas.

I worry that the W2AU may be more than a center conductor

Hi Cecil

> Continuing after taking my wife to work:

Yo have a chopper, I have a chopper. Your wife go to work, my wife go
to work. Are you my big brother? (older brother? => "hermano mayor",
in spanish) :>D
...
> Dr. Corum tells us what the problem is: "Lumped circuit theory fails
because it's a *theory* whose presuppositions are inadequate.

Well... "theories" are theories, models of "reality". As Einstein
said: "free creations of the human mind" => Newton's gravity theory,
Einstein's gravity theory...
Einstein one of course it is more accurate in certain situations, but
we still using Newton's laws to send spacecrafts to Mars. As in the
Sears-Zemansky example given, they coexist and it can solve differents
problems.
Velocity adding fails at very high speeds ("presuppositions are
inadequate") and we need relativity, but for common situations it is
not necessary use the last one (of course you know it, it is only a
note). It is easy for us become tempted to think that Einstein one it
is the "true" theory and not "a better aproximation to reality"
theory.

As some of us agree "all models are false", then, perhaps --only
"perhaps"-- (I do not want offend to anyone) some of the others models
presented by our distinguished colleages could not be as precise for
certain special situations, but still quite adequate to solve problems
or explain more simple things, as a Newton laws or "charges in
movement"...

As in other physics laws, it is not possible to reach a similar consensus here in this regard? Models given, leads to wrong numbers or failed to agree with empiric data?

Your examples, Cecil, gve me a light, now I have in my mind three models that (for me) describe "reality" so good. With yours I can think in forward and reflected power flowing simultaneously on Rs -not contradiction-
Adding phasors of the forward and reflected travelling waves before the last one reach generator, this one sees different Z line input and not any reflected power there is circulating on it (not contradiction to me) => "adding" in my human mind, of course. Reality only God/Allah/ Yahweh/Manitou/The Force/Zeus, knows- :>) .

I'm not trying to be syncretic. Same cat, different models... Is it not possible that?

Hi Miguel,

You are welcome.

My comments (beyond your quote above) were in regard to you observing
the amount of time Walt's topic has been under discussion. In fact,
the agony of source resistance has been painfully with us for as long
as newsgroups could support the noise bandwidth.

As dangerous as unasked-for advice is, prepare something at your bench
to measure all these contentious issues for yourself. Force the
issues that are only being discussed rather than measured. Discover
the roots of what used to be a "hands on" avocation. Learn the
practical reality in relation to the academic meaning. Discover the
first principles by making mistakes and having failures that you can
correct in front of you, instead of being assisted by an "expert."
Compare results with like-minded bench workers who can perform the
same examinations you are doing.

This is what Walt did - many times. His bench work eclipses ALL
discussion of theory. The irony that inhabits this is that his bench
work may even eclipse his own explanations. Absolutely no one else
has dared to slide up to the bench to demonstrate that, however. The
level of "critique" is much like ants scattering at the feet of a
giant.

There is a lot of math thrown against the wall to prove something. It
may or may not be the same thing. What it does prove is:
"Models are doomed to succeed."
This is demonstrated here at least once a week on average, and is even
held up as a hallmark of hazing, initiation, or anti-intellectual
snobbery. Math/Models/Simulations/Theories serve many religious wars.

"For the most part, "maximum power transfer is just an interesting ideosyncracy of linear circuit theory."

In the world of 50 and 60 Hz, we don`t want all the power plant can supply when we flip on a light switch.

The RF world is usually different.

Maximum power transfer only occurs when source and load match conjugately, and the match proves the load and source impedances are equals. It is well known and easily shown that a match results in maximum power transfer.

If one has a 100-watt transmitter he probably wants 100 watts out of it sometimes and may only be able to do so when his antenna is matched to his transmitter,

Maxumum power treansfer is more than an "interesting ideosyncracy".

It's also easily shown that it doesn't.

Consider a 10 volt voltage source having a 50 ohm source resistance,
feeding a 50 ohm resistive load. Power at the load is 0.5 watt, is it not?

Reduce the source impedance to 10 ohms.

Now what is the power dissipated in the load?
Is it greater or less than it was when the source and load impedances
were matched?

Yes, except that W7EL uses the inadequacy of his model to prove that
his model yields contradictory results. I freely admit that his model
is inadequate and contradictory which implies that he is using the
wrong model.

unfortunately bill, art suffers from short memory also among his other
debilities. it has been explained to him several times by different
people that gauss'es law is perfectly applicable to both static and

varying fields without his 'improvement', he just can't remember it
from day to day.

> the output power.

Of course the grid drive is one of the factors which controls the
current flowing in the load.

But the power supply is also one of the limiting factors. Reducing
the power supply voltage below that which is necessary to cause the
desired current to flow in the load will reduce the power output.
Similarly, increasing the load resistance will eventually raise it to
the point where the voltage is no longer adequate to cause the desired
current to flow.

> Second, the tank circuit is an energy storage device that isolates the

> circuit.

Can one not have a linear circuit where the current and voltage are
not
in phase? Also, if one loads any tank circuit with a resistance, the
output current and voltage will be in phase and if it is loaded with
a
reactance, they won’t be.

> The effect of the energy storage of the tank results in the
> tank becoming the source of the energy appearing at the output.

Yes, but that does not make the output independent of the input.

> Third, the action of plate resistance Rp occurs only in the formation

I do not understand what is being said here.

> the theorem of Maximum Transfer of Power.

The definition I use for conjugate match is one where the source
impedance is the complex conjugate of the load impedance. When this
situation occurs between linear networks, maximum power is transferred
between the networks.

None-the-less, just because maximum power is being transferred between
two networks does not mean they are complex conjugates of each other.
This is demonstrated with the non-linear behaviour of the bench power
supply example. Maximum power is transferred but the source and load
impedance are not complex conjugates.

> Fifth, as I stated earlier, when the reactance appearing at the input

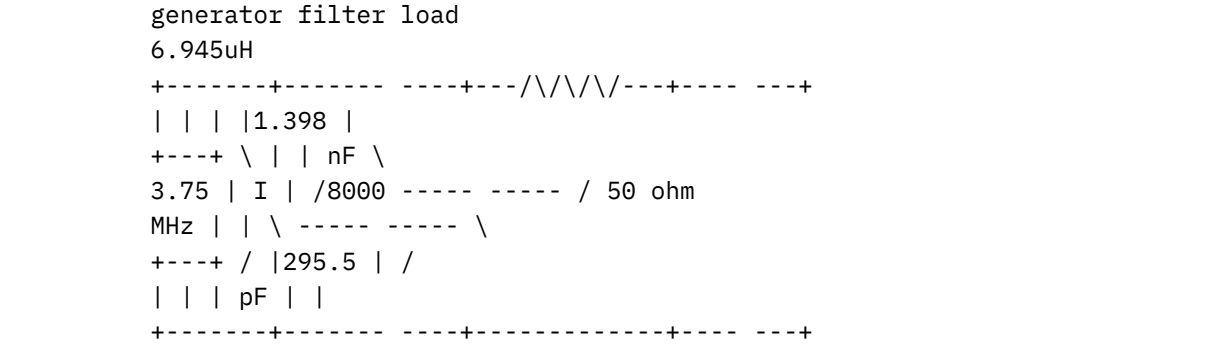
> of the line-input impedance. If you cannot accept this as fact you
> have a problem.

Perhaps I am not computing the impedances correctly. Let us see if I
have done so for the following example.

Consider a generator constructed of current source in parallel with
a resistor, driving a PI network, connected to a load.



Looking into the input of the filter, then impedance is 1500 ohms.
This is the load applied to the generator and is computed by
applying the rules for series and parallel components to
the 50 ohm load, and the two capacitors and inductor in the PI
network.

It is, I hope, generally accepted that the generator will have an
output impedance of 8000 ohms.
The output impedance of the filter is computed by applying the
rules for series and parallel components to the 8000 ohm
generator impedance and the 3 components in the filter.
The result is 58.00 /_ 68.60 ohms.

Note that the component values were taken from a PA design where
the desired load for the tube was 1500 ohms. And 8000 is not an
unreasonable slope for the plate E-I curve of a tube.

This has not resulted in a conjugate match.

> Sixth, your understanding of the effect of the reflected wave on the

> on the voltage current relationship is linear. If you cannot accept
> this as fact you have still another problem.

It is, perhaps, this claim of isolation that is most strange. It seems
quite at odds with the rules for connected networks.

> Seventh, your belief that because there is a conjugate match at the

> tank is also not true. The effect of the energy storage in the tank
> isolates the non-linearity af the input from the linear operation at
> the output, permitting a conjugate match at the output, while not
> allowing it to occur at the input.

It was my understanding that in a sequence of connected linear
networks, if any connection exhibited a conjugate match, then they
all were conjugately matched. Is this not correct?
Are you saying that if a conjugate match is present between the line
and the antenna, it might not be present between the transmitter and
the line?

> These seven comments are born out (proven) by the results of many

> my position.

I quite believe your measurements. It is the conclusion that they
prove a conjugate match that I find impossible to accept. Both
because there are other situations that can lead to power behaviours
that may appear similar to the power behaviour of a conjugate match
and the method proposed for computing source impedance is quite at
odds with linear theory.

But the quality of the measurements suggest it is worthwhile to
explore other explanations.

But Roy, consider that the source resistance remains constant at 10 ohms. Then what load resistance will absorb the most power? The answer is 10 ohms. Any value of load resistance greater or less than 10 ohms will result in less power delivered. I don't believe it's fair to change the source resistance when dealing with the Maximum Power Transfer Theorem.

In your example with a source resistance of 10 ohms and a load resistance of 50 ohms the power delivered will be 1.39 watts. But when the load resistance is 10 ohms with the same source resistance the power delivered is 2.5 watts. As I said above, if the load resistance is either greater or less than 10 ohms the power delivered will be less than 2.5 watts. Thus when the source resistance is constant the maximum power will be delivered when the load is matched to the source.

I see no hostility from you Bill. But there has been a lot of
hostility to my proposed theorem. Just following Newtons laws for
equations that when all is summed it must equal zero. This is no
different that allowed an addition of displacement current by Maxwell.
Same goes for all boundary laws with respect to Newton whether they
may be static or dynamic. Now in the case of Gauss and Newton
each had different units because of a change in standards so authors
never bothered or was to lazy to do the excercise. As it happens if
one did go thru with the excersise you will find that the dynamic form
of Gauss's law is exactly the same as Maxwells laws for propagation.
Just think if any author had taken this step we would never have had
the discussions of waves versus particles that have held up the
explanation of accelleration of charge which is propelled by the
intersection with displacement current! This group initially rejected
everything because I inferred the connection of static fields with
propagation which they just could not accept. And for good reason in
that it is not explained in any books. When I used an optimizer
program based solely on Maxwell I expected an array in equilibrium
which is what I got. In addition the array supplied by the program
reflected the equal and opposite arrangement of vectors supplied by
gravity and earths rotation where these same two vectors continue thru
out the Maxwell /Gauss equation all the way back to the big bang when
equilibrium was broken momentarily where a particle escaped with the
addition of spin. All this was what Einstein was searching for and
showed how a particle/charge was supplied with accelleration and spin
such that there was straight line trajectory that was not impinged
upon by gravitational effects. From all these matching sections and
interactions I saw that the Neutrinos was the particle in question
because it is of the smallest mass known and because of this the speed

of light can be ascertained. Now we have the accelleration of the neutrinos (CERN and FERMILAB) and consequential impacts which sort of infers that the neutrinos can shatter into smaller amounts of mass of that which was accellerated at the speed of light which I really don't understand. We also have the notion of a photon detaching itself from a Neutrinpos for the purposes of light which states that this aproach means the formation of a photon that has no mass the possibility of which has not been proved. Frankly physics has to go back to classical physics where it is confirmed that the idea of waves was an error that held physics back for so long. At least now we have a progresion of events that satisfies Maxwells equations in every respect that requires no new laws and only the adherence to existing laws of the masters where the presence of equilibrium is demanded as with all laws. The cream of the theory came when I used a program devoted solely to the requirements of Maxwell and it provided a non planar design where equilibrium was adhered to and the vectors involved were opposite to those involved outside the boundary containing our Earth.

Of course, I know that, and I would hope anyone with even very basic electrical circuit analysis knowledge does. And anyone with that knowledge should state as you have,

"FOR A GIVEN SOURCE IMPEDANCE, maximum power transfer occurs when the source and load impedances are matched (i.e., the load impedance is the complex conjugate of the source impedance)," which is true.

But the statement which was made was that "Maximum power transfer occurs when the source and load impedances are matched." This is NOT true, as the example demonstrates.

It's an important distinction. Instead of declaring what's "fair" and what isn't with regard to changing source and load impedances, the maximum power transfer theorem should be stated correctly, in a way which makes it true.

If you are uninterested in source impedance (and many people seem
to be much more concerned with it than they need to be), then
by all means do not consider it, do not specify it, do not attempt
to compute it or measure it and do not make statements about what
the source impedance is.

But if source impedance is of concern for a particular application,
then please do compute and measure it properly.

no, you still can't say that... the equation still applies to fields
just like it always did.

The theorem requires linear *lossless* networks which do not exist in reality, i.e. networks containing only reactances. Therefore an *ideal* system-wide conjugate match cannot exist in reality just as a lossless transmission line cannot exist in reality. In low-loss systems, we can only achieve a system-wide near-conjugate match with an ideal conjugate match existing at one point, e.g. the Z0-match point where reflected energy flowing toward the source is eliminated.

> Are you saying that if a conjugate match is present between the line
> and the antenna, it might not be present between the transmitter and
> the line?

Yes, speaking for me, in the real world, it is easy to prove that the system-wide impedance looking in one direction is not always exactly the conjugate of the impedance looking in the other direction. Thus the "maximum power transfer" assertion has to be modified to "maximum *available power* transfer". In the real world, ohmic and dielectric losses reduce the power available to be delivered to the load.

It's easy to see. Let's say we have a completely flat 50 ohm system; 50 ohm source, 50 ohm coaxial feedline, and 50 ohm antenna. Now assume we install an antenna tuner between the source and the feedline that exhibits some series impedance and we adjust the tuner such that the source sees 50 ohms. At the output of the tuner looking toward the antenna, we will see 50 ohms. Looking back through the tuner toward the source, we will see the tuner impedance in series with 50 ohms. That proves it is not an *ideal* (lossless) conjugate match although it may be considered to be a near-conjugate match, as close as we can come in the real world.

What I don't know is how close a real-world conjugate match has to be to an ideal lossless conjugate to be called a "conjugate match". A purist might argue that an ideal conjugate match cannot exist in reality. A realist might argue that if we are within 10% of an ideal conjugate match, then it is a real-world conjugate match, by definition.

Note that I am not speaking for Walt here, just for myself.

The question then becomes: If the system box does not include the
source and the system exhibits characteristics consistent with a
conjugate match, can we say the system is conjugately matched? For
instance:

100V---50 ohm coax---+---1/4WL 300 ohm feedline---1800 ohm load

This system exhibits all the characteristics of a conjugately matched
system. Can we say it is conjugately matched?

Excuse me Cecil:

I am reading this newsgroup through Google groups web page and I just realized that later replies to previous post are intercalated in the thread, while I expected to see it always at the end of it, for that reason I did not ACK before to it. (I hope yours be the only one, I will review all thread tho chek for others).

In a early post I wrote => "of course if we insert a circulator to separate both powers, generator now would see 1 ohm load, could develope 1 W incident, 0 W reflected (Pn=1W) on circulator input, 0.36 W would be outputting on the other port to render 0.64 W (Pn) to the load with 1 W Pf and 0,36 W Pr again"
Is this result OK for you?.

The thread advance toward more deeper issues since :>), and now I have been analizing all the matter because it quickly superceed my original doubt. A few minutes ago had started to read your article (http://www.w5dxp.com/energy.htm) and the Roy's one (http://eznec.com/misc/Food_for_thought.pdf) and yesterday I have been reloading my old "Transmission lines antennas and wave guides" from King, Mimno & Wing to review the issue from that classical perspective.

I am interested in your optic analogy, I can imagine the load as a partially reflecting surface, real part of it as absorbance (transmittance if it was a radiator). line as a unidimensional medium and reflection as the form of "redistribute energy" (is it OK?) and a coherent light source for the voltage source, but I am still trying to visualze the optical equivalent of source resistance and its job to be a good analog, Also I am interested in check other values and conditions in your other article (first part) with 45 degree line.

Thank you very much for your helping and inspiration.

Nope, what we can say is that waves and their associated particles are dual manifestations of the same physical phenomena. There is no difference between an EM wave and a photonic wave and individual photons exhibit electromagnetic wave properties. What is important is that one can double the energy magnitude by adding, in phase, one photon to one photon. But one cannot halve the energy magnitude by cutting a photon in half.

It is easy to identify individual photons in an EM wave, especially at the higher (light+) frequencies. Not so easy is identifying individual photons in the static magnetic field from a permanent magnet. :-o

I am also using Google since ATT dropped Usenet. I liked Thunderbird a lot better than Google's usenet interface but I am adapting. The above information is good to know. Thunderbird has a way to keep up with unread vs read postings but Google doesn't seem to - at least I don't know how to do it on Google.

> Is this result OK for you?.

The SGCR source is usually designed for 50 ohms, i.e. the signal generator always "sees" a 50 ohm load because it does not "see" any reflected energy. The ideal circulator is usually designed with 50 ohm line and a 50 ohm load resistor. If we could stick with that particular configuration for the SGCR source, it would aid in my understanding what is the actual system configuration, i.e. not your fault but I am confused by your above posting.

I don't think a laser source handles reflected energy like an RF amp does. So, to start with, let's avoid reflected energy being incident upon the laser source. Here is a good example to start with, a 1/4WL non-reflective coating on glass.

Laser-----air-------|--1/4WL thin-film, r = 1.2222---|---Glass, r = 1.4938---...

The 1/4WL thin-film coating on the glass acts exactly like a 1/4WL matching section of transmission line. Reflections at the air to thin-film interface are eliminated by wave cancellation just as the FSU web page says,

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are 180-degrees ... out of phase with each other meet, they are not actually annihilated, ... All of the photon energy present in these waves must somehow be recovered or redistributed in a new direction, according to the law of energy conservation ... Instead, upon meeting, the photons are redistributed to regions that permit constructive interference, so the effect should be considered as a redistribution of light waves and photon energy rather than the spontaneous construction or destruction of light."

Note that the reflection coefficient, r, is 1.0 for air. Thus the SQRT[(1.0)(1.4938)] = 1.2222 ensures that reflections are eliminated by the r = 1.2222 thin-film coating.

The same thing happens at the '+' Z0-match in the following RF system.

XMTR---50 ohm coax---+---1/4WL 300 ohm feedline---1800 ohm load

Note that SQRT[(50)(1800)] = 300 ensuring that reflections are eliminated.

> Also I am interested in check other values and
> conditions in your other article (first part) with 45 degree line.

Sorry, I forgot to comment on this. If the line length is fixed at 45 degrees, the reflected wave arrives back at the 50 ohm source resistor 90 degrees out of phase with the source's forward wave. When two waves are 90 degrees out of phase, there is zero interference between them because cos(90) = 0 and the interference term in the following equation disappears.

Ptot = P1 + P2 + 2*SQRT(P1*P2)cos(theta)

There is no re-reflection of the reflected wave from the 50 ohm source resistor because it matches the coax Z0. There is no redistribution of constructive/destructive interference energy because there is zero interference. Therefore, for the special case where Vfor is 90 degrees out of phase with Vref at the source resistor, all of the reflected power will be dissipated in the source resistor.

If the interference at the source resistor is constructive, i.e. less than 90 degrees difference between Vfor and Vref, the power dissipated in the source resistor will be all of the reflected power plus some of the source power.

If the interference at the source resistor between Vfor and Vref is destructive, i.e. between 90 degrees and 180 degrees, some of the reflected power will be redistributed (by wave cancellation) back toward the load.

Note that the I and Q method of transferring two streams of information on the same carrier relies on this same no interference (at 90 degrees) concept.

I am wondering how a wave, light, can be affected by a black hole as has
been seen by the Hubble space telescope. This goes deeply into the
nature of light it self, like how is a wave with no real mass affected?
We need researchers pushing the boundary, and if others don't understand
it then let them step aside.

From all these matching sections and

This is where I get into it, Photons are just a way to explain something
to the masses of people who can nor understand the true nature of light.
CERN has, I think, two counter rotating beams that can cause a crash at
nearly twice the speed of light.
New and non-naturally formed particles, some with a life time measured
in nano seconds.

Frankly physics has to go back to classical

Photons have mass because of their velocity (speed of light). m = E/
c^2 Photons have no rest mass but they are never at rest. An
experiment long ago proved Einstein to be correct when he claimed that
light was affected by gravity. A black hole is no exception.

http://en.wikipedia.org/wiki/Gravitational_lens

> Frankly physics has to go back to classical

How would classical physics explain how a single particle can go
through two slits at the same time and interfere with itself on the
other side? This phenomenon includes photons, electrons, and
apparently includes relatively massive Bucky Balls made up of many
carbon atoms.

How would classical physics explain how entangled particles remain in
instantaneous contact no matter how far apart they are? This seems to
violate the spirit (if not the letter) of the speed-of-light limit.

FYI, It appears that Google has a "Reader" available at the top of the
web page, that has the mark-as-read/unread ability with which one can
keep track of the read/unread postings.

I probably should not have breached the subject since it will be a war
of opinions. If light was indeed a particle (photon) it could be
affected, but light is just really super high frequency radio in nature.
Radio is not particulate so why the hang-up over photons???

And are this true: "We also assumed, perfectly arbitrarily, that the
direction of these vortices is such that, on looking along a line of force
from south to north, we should see the vortices revolving in the direc- tion
of the hands of a watch. We found that the velocity of the circumference of
each vortex must be proportional to the intensity of the magnetic force, and
that the density of the substance of the vortex must be propor- tional to
the capacity of the medium for magnetic induction." From:
http://en.wikisource.org/wiki/On_Physical_Lines_of_Force

"the density of the substance of the vortex "
As you see in Maxwell's hypothesis was the mass. The all waves need mass and
inertia.
But all movements (also waves) can be described dynamically (with mass) or
geometrically (only directions and speed).
The famous Heaviside's equations are the geometrical description of the
waves.

Roy Lewallen, W7EL wrote:
"Nut the statement which was made was that "Maximum power transfer occurs when the source and load impedances are matched."

Inelegant and bereft of qualifications as it may be, I am the author of that statement, and I stand by it.

Roy says: "This is not true, as the example demonstrates."

Robert L. Schrader says on page 43 of "Electronic Communication":
"To produce maximum power in any load, it is necessary that the load resistance equal the internal resistance of the source."

I believe our statements are equivalent. Load a battery of a given internal resistance with the same resistance as a load, and for a short time the battery will deliver more power to that load than to any other resistance larger or smaller.

Best regards, Richard Harrison. KB5WZI

Roy Lewallen wrote:
"Reduce the source imperance to 10 ohms."

FOUL!

In the case of a 10-ohm internal source, the load which extracts maximum power is 10 ohms.

Quoting Roger Miller from the movie: "Water Hole Number Three"; "If
fishes had wishes, they'd fly".

Actually, it has nothing to do with opinions and everything to do with
actual experiments. EM wave energy, which includes visible light and
RF waves, has been proven beyond any doubt to be quantized which
implies a particle nature and not a continuously variable analog
field. In fact, quantum electrodynamics, which has an uncanny ability
to predict sub-atomic physics experimental outcomes, tells us that
nothing can exist outside of its existence as a particle. Have you
ever tried to prove that something can actually exist without a
particle nature being involved?

From the lowest level of light detectable by the human brain, the next
step up in brightness is 11.1111% greater than that first level - not
0.000001% as your opinion seems to desire. Following is the URL for an
interesting paper on the subject.

Over the last few years a I have started preferring using the folded
dipole for the driven element also. I dont understand your need for
4:1 BALUN though.

Source record: 9697

I stand by my position that when the source is an RF power amplifier, and when all the available power is transferred from the source to the load, the source impedance is the conjugate of the load impedance. In a similar instance, if the load is a pure resistance, the source resistance equals the load resistance.

And referring to a statement Dysart made concerning plate resistance, Rp, it must be understood that in Class AB, B and C amplifiers, Rp is NOT the source resistance. In those amplifiers the effect of Rp is a negative feedback that reduces the effect of plate-current change resulting from a change in grid voltage, thus reducing the power output compared to what the output would be if Rp were absent. Compensation for the power lost to Rp is accomplished by simply increasing the grid drive.

Consequently, Rp plays no part in achieving a conjugate match at the junction of the network-output and the load. Although lossless elements are required to achieve a perfect conjugate match in both directions, a perfect conjugate match is obtained in the forward direction with real elements when all available power is being delivered to the load. This condition is verified in data presented in Chapter 24 of Reflections 3.

Walt, W2DU

another robust one is the T match as used in old telrex yagis. it is
dc grounded and needs no capacitor, but it does use a 1/2 wave 'balun'
or phasing line between the halves of the T.

Hi Richard. thanks for your reply.

I recognize so much the Walter's work as I said in my initial post. "Another look at reflections" was one of the my most appreciated readings of my early days as student and Ham.
But without wishing to be flattering ("adulador" in spanish), I feel in debt with much others works from you (all) (I do not give more names to not commit injustice omiting anyone).
I believe you are a gifted, brilliant, intelligent and supportive Hams sharing your knowledge and experience with us. For that, I am/we are indebted to all of you :>)

However, I believe for all reasons given above, you will be capable to arrive to a good technical/scientific consensus about the matter. We trust in your ability and capacity to get it.
This is very important for us because not all are capable to develop theory from empirical working and we need your agreement to study things that in my experience are very difficult to grasp even for university graduates...

> resistance for a Class A amplifier?

Keith,

Assertions have been made about the Thevenin equivalent source impedance (Zs) of an RF PA. In the discussions over the years, some people have imposed some qualifications (eg classes, tuned / untuned etc).

Zs can be measured by a number of methods. It is interesting to note that in many of the discussions on the 'net on this topic, more focus is given to dismissing the experiment design for experiments that produce unfavourable results to some, than questioning the proposition that Zs is 50+j0 or thereabouts.

Whilst Walt has documented a quite rigourous experiment, and it produced a favourable outcome, it is my view that that in itself is not proof of the proposition.

Whilst one favourable experiment cannot proove the proposition correct, just one valid experiment can prove the proposition to be not generally true. No doubt the reason for the focus on proving experiments invalid.

If you give some thought to what you could use Zs for, then every valid experiment that is designed around that application must produce a favourable outcome if Zs is as proposed. If they don't, then the value assumed for Zs must be wrong.

I posted a simple test earlier that in my experience does not support the proposition that typical ham HF transmitters have Zs=50+j0 or close to it. The test is documented so that individuals can try it and make their own mind up. Some might get favourable results on limited trials... but in my view, that is outweighed by unfavourable results from valid experiments.

Message-ID: <IuGdnf-t55G3jWLWnZ2dnUVZ_h-dnZ2d@islandhosting.com>
Source record: 9556

Hi, Folks.

Looking for some advice.

I want to create a grounded opening in the wall of my ham shack through which I'll install each rf cable that enters the shack. I plan to bolt a conductive plate to the wall ground that I'll fasten the ground side of each coaxial cable to, then bolt a ground cable to each ground rod and the plate.

Is there a significant difference between using the galvanized steel ground rods and copper to create an rf gound? The copper ones are more than double the price - is it worth using them?

Thanks, Bob, VE7HS

Hi Miguel,

A nice sentiment, but even the most silvered authorities disagree. One
has only to look at the relativist camp vs. the quantum camp in
nuclear physics.

>This is very important for us because not all are capable to develop

Then, this will be dissappointing. University is for finding your own
way, and that does not come without regrets. There's a maxim that
applies here:
"If you haven't failed, you are not trying hard enough."

Now just hold on right there!
As I have stated before, wave is a descriptive word
and not a noun as described by a particle. Just as a
amount of moisture does not become equal to a cloud. You are using
existing positions and theories
without the required accompanying proof
The truth is that none of the existing theories stand up to
examination to explain the phenomina of radiation upto and including
the super string theory.
Thus they are all suspect in one way or another.
Right at the very beginning I used Gauss's definition to describe a
particle, no where is the term wave mentioned Now we come to Maxwells
equations he also does not mention waves because he is considering a
instant of time which includes every function required to perform the
function of displacement of a particle as refferred to by Gauss. He
also reinforced the idea of equilibrium per Newtons laws by assuring
that all components involved in the equation equalled zero.
Thus one can say using long existant rules that what is made dynamic
must also be resonant and where the sum is in equilibrium. Now all the
expressions you are using comes from discredited theories, where as
mine comes from the existance of the Newtons boundary rules, gaussian
postulate and and the combination of many inputs from the masters of
that time that provided Maxwells laws.
I am just using the existing classical rules of the day
nothing is new and there is no reinvention of any kind.
So I put it to you again that it unreasonable to quote
hypothesis that have been proved not up to the task
and to not provide supporting reason to discredit Maxwell,Gauss and
the other masters on whose shoulders we stand on today. Forget about
your beloved photons which you habitually use as a shell game to
confuse onlookers and review which is considered correct up to "this
particular point" instead of making giant hops up the ladder of
knowledge like jumping the Grand canyon in two jumps. If you have good
reason to diss the work of the masters then I am sure others will want
to hear about it.
Best regards, nothing personal intended

Yes Richard. I agree, however I said "even for graduated" ("aún para
graduados" in spanish), but this a radio Amateur group, isn't it...
Hey Richard, do not be hard with us :>) your helping is important and
valuable for hundred (if not thousands) of present an future Amateurs.
Thanks again.

Miguel

May we advance in little steps to ensure we share basic assumptions?

1) I did not think of (or is think on?) a laser source, I was one step before, I think only of a "coherent" source to match monofrequency simple AC generator analogy.
2) What would be Rs optical analog?
3) Superposition is a medium phenomenon ¿yes?, for example "eter". Interference an result of it on a other "thing", for example photographic plate or screen. Are we agree? K

Owen, I have reviewed your simple test using an ATU to obtain various load impedances, but I don't see any data showing the results of any tests you may have made using this procedure. I'm assuming it's the same procedure I used in measuring the data I presented in Chapter 19 of Reflections 2, in which I varied the load impedance by switching between two different, but closely related values of load resistance.

Unless we're discussing RF power amps using solid-state components, I don't understand why anyone would expect the source impedance to be 50 + j0 ohms unless the source was delivering all its available power into a 50 + j0 load.

I've made an addition to Chapter 19 as it appears in Reflections 2. That addition now appears in the new edition, Reflections 3. In that addition I report the procedure and results of measuring the output impedance of a Kenwood TS-830S terminated in a complex load of 17.98 + j8.77 ohms. I described fourteen steps in the procedure that resulted in the measured output impedance of the Kenwood to be 18 - j8 ohms, which is sufficiently close to the conjugate of the load to be a practical conjugate match between the source and load impedances.

Why then do you discount the data from my measurements as not proof that the 18 - j8 ohms of source impedance is valid?

I'm going to try to insert a copy of the 14 steps of the procedure. However, as I have tried this type of insertion previously and failed, it also may fail here. If it fails I invite you to go to my web page at www.w2du.com and click on the line "Preview Chapters from Reflections 3" and then click on Chapter 19A, then scroll down to Sec 19A.5 Additional Experimental Data. There you will see the detailed description of the entire procedure. I hope this will help in understanding my posistion concerning the measurement of the source impedance at the output of the tank circuit of an RF power amplifier.

Sec 19.14 Additional Experimental Data

The source resistance data reported in Secs 19.8 and 19.9 were obtained using the load variation method with resistive loads. Note that of the six measurements of output source resistance reported in Table 19.1, the average value of the resistance is 50.3 ohms obtained with the reference load resistance of 51.2 ohms, exhibiting an error of only 1.8 percent. However, various critics assert that proof of a conjugate match between the source and load requires the load to contain reactance. Accordingly, the experimental data reported below were obtained using both the load variation method and an indirect method for determining the source impedance of the RF power amplifier, with a resistive load to obtain a reference source resistance and a complex load to determine the complex source impedance that is then proven to be the conjugate of the complex load.
We’ll now examine the experimental data that resulted from measurements performed subsequent to those reported in Secs 19.8 and 19.9, new data that provides additional evidence that a conjugate match exists at the output terminals of an RF power amplifier when all of its available power is delivered into its load, however complex the load impedance. According to the definition of the conjugate match as explained in Sec 19.1, Axioms 1 and 2, if this condition prevails there is a conjugate match. In addition, the data presented below also provides further evidence that the output source resistance of the RF amplifier is non-dissipative. The following steps describe the experimental procedure I employed and the results obtained:

1. Using a Kenwood TS-830S transceiver as the RF source, the tuning and loading of the pi-network are adjusted to deliver all the available power into a 50 + j0-ohm load with the grid drive adjusted to deliver the maximum of 100 watts at 4 MHz, thus establishing the

area of the RF power window at the input of the pi-network, resistance RLP at the plate, and the slope of the load line. The output source resistance of the amplifier in this condition will later be shown to be 50 ohms. In this condition the DC plate voltage is 800 v and plate current is 260 ma. DC input power is therefore 800 v ☐ 0.26 a = 208 w. Readings on the Bird 43 wattmeter indicate 100 watts forward and zero watts reflected. (100 watts is the maximum RF output power available at this drive level.) From here on the grid drive is left undisturbed, and the pi-network controls are left undisturbed until Step 10.

2. The amplifier is now powered down and the load resistance RL is measured across the input terminals of the resonant pi-network tank circuit (from plate to ground) with an HP-4815 Vector Impedance Meter. The resistance is found to be approximately 1400 ohms. Because the amplifier was adjusted to deliver the maximum available power of 100 watts prior to the resistance measurement, the averaged resistance RLP looking into the plate (upstream from the network terminals) is also approximately 1400 ohms. Accordingly, a non-reactive 1400-ohm resistor is now connected across the input terminals of the pi-network tank circuit and source resistance ROS is measured looking rearward into the output terminals of the network. Resistance ROS was found to be 50 ohms.

3. Three 50-ohm dummy loads (a 1500w Bird and two Heathkit Cantennas) are now connected in parallel to provide a purely resistive load of 16.67 ohms, and used to terminate a coax of 13.5° length at 4 MHz.

4. The impedance ZIN appearing at the input of the 13.5° length of coax at 4 MHz terminated by the 16.67-ohm resistor of Step 3 is measured with the Vector Impedance Meter, and found to be 20 ohms at ☐ +26°. Converting from polar to rectangular notation, ZIN = 17.98 + j8.77 ohms. (ZIN = ZLOAD from the earlier paragraphs.) This impedance is used in Steps 5 and 6 to provide the alternate load impedance in the load-variation method for determining the complex output impedance of the amplifier, and for proving that the conjugate match exists.

5. With respect to 50 ohms, ZIN from Step 4 yields a 2.88:1 mismatch and a voltage reflection coefficient rho = 0.484. Therefore, power reflection coefficient rho^2 = 0.235, transmission coefficient (1 − rho^2) = 0.766, and forward power increase factor 1/(1 − rho^2) = 1/0.766 = 1.306.

6. Leaving pi-network and drive level adjustments undisturbed, the 50-ohm load is now replaced with the coax terminated with the 16.67-ohm load from Step 4, thus changing the load impedance from 50 + j0 ohms to 17.98 + j8.77 ohms, the input impedance ZIN of the coax.

7. Due to the 2.88:1 mismatch at the load, neglecting network losses and the small change in plate current resulting from the mismatch, approximately the same mismatch appears between RLP and ZL at the input of the pi-network. Consequently, the change in load impedance changed the network input resistance RL from 1400 ohms to complex ZL =

800 – j1000 ohms, measured with the Vector Impedance Meter using the method described in Step 2. To verify the impedance measurement of ZL the phase delay of the network was measured using an HP-8405 Vector Voltmeter and found to be 127°. Using this value of phase delay the input impedance ZL was calculated using two different methods; one yielding 792 – j1003 ohms, the other yielding 794.6 – j961.3 ohms, thus verifying the accuracy of the measurement. However, although grid voltage EC, grid drive EG, are left unchanged, resistance RLP of approximately 1400 ohms at the plate has changed somewhat due to the small changes in plate voltage and plate current due to the change in the load, leaving a mismatch between RLP and ZL at the input of the pi-network. As stated above, this value of ZL yields the substantially the same mismatch to plate resistance RLP as that between the output impedance of the pi-network and the 17.98 + j8.77-ohm load, i.e., 2.88:1. This mismatch at the network input results in less power delivered into the network, and thus to the load, a decrease in the area of the RF window at the network input, and a change in the slope of the loadline. (It must be remembered that the input and output mismatches contribute only to mismatch loss, which does not result in power delivered and then lost somewhere in dissipation. As we will see in Step 8, the mismatch at the input of the pi-network results only in a reduced delivery of source power proportional to the degree of mismatch.)

8. Readings on a Bird 43 power meter now indicate 95w forward and 20w reflected, meaning only 75 watts are now delivered by the source and absorbed in the mismatched load. The 20w reflected power remains in the coax, and adds to the 75 watts delivered by the source to establish the total forward power of 95w.

9. We now compare the measured power delivered with the calculated power, using the power transmission coefficient, 1 – rho^2. The calculated power delivered is: 100w x (1 – rho^2) = 76.6w, compared to the 75w indicated by the Bird wattmeter. However, because the new load impedance is less than the original 50 ohms, and also reactive, the amplifier is now overloaded and the pi-network is detuned from resonance. Consequently, the plate current has increased from 260 to 290 ma, plate voltage has dropped to 760 v, and DC input power has increased from 208 w to 220.4 w.

10. With the 17.98 + j8.77-ohm load still connected, the pi-network loading and tuning are now re-adjusted to again deliver all available power with drive level setting still left undisturbed. The readjustment of the plate tuning capacitor has increased the capacitive reactance in the pi-network by –8.77 ohms, canceling the +8.77 ohms of inductive reactance in the load, returning the system to resonance. The readjustment of the loading control capacitor has decreased the output capacitive reactance, thus reducing the output resistance from 50 to 17.98 ohms. Thus the network readjustments have decreased the output impedance from 50 + j0 to 17.98 – j 8.77 ohms, the conjugate of the load impedance, 17.98 + j8.77 ohms. The

readjustments have also returned the network input impedance ZL to 1400 + j0 ohms (again equal to RLP), have returned the original area of the RF window at the network input, and have returned the slope of the loadline to its original value. For verification of the 1400-ohm network input resistance after the readjustment, ZL was again measured using the method described in Step 2, and found it to have returned to 1400 + j0 ohms.

11. Bird 43 power meter readings following the readjustment procedure now indicate 130w forward and 29.5w reflected, indicating 100.5w delivered to the mismatched load.

12. For comparison, the calculated power values are: Forward power = 100 x 1.306 = 130.6w, reflected power = 30.6w, and delivered power = 130.6w – 30.6w = 100w showing substantial agreement with the measured values. (1.306 is the forward power increase factor determined in Step 5.) Plate current has returned to its original value, 260 ma, and likewise, plate voltage has also returned to the original value, 800 v. Consequently, the DC input power has also returned to its original value, 208 w.

13. It is thus evident that the amplifier has returned to delivering the original power, 100 watts into the previously mismatched complex-impedance load, now conjugately matched, the same as when it was delivering 100 watts into the 50-ohm non-reactive load. But the reflected power, 30.6 watts, remains in the coax, adding to the 100 watts delivered by the amplifier to establish the 130.6 watts of forward power, proving that it does not enter the amplifier to dissipate and heat the network or the tube.

It must be kept in mind that impedance ZIN appearing at the input of the 13° line connecting the 16.7-ohm termination to the output of the amplifier is the result of reflected waves of both voltage and current, and thus reflected power is returning to the input of the line, and becomes incident on the output of the amplifier.
The significance of these measurement data is that for the amplifier to deliver all of its available power (100w) into the mismatched load impedance ZIN = 17.98 + j8.77 ohms, the readjustment of the tuning and loading of the pi-network simply changed the output impedance of the network from 50 + j0 ohms to 17.98 – j8.77 ohms, the conjugate of the load impedance, thus matching the output impedance of the network to the input impedance of the coax. Consequently, there is a conjugate match between the output of the transceiver and its complex load. QED. The readjustments of the pi-network simply changed its impedance transformation ratio from 50:1400 to (17.98 – j8.77): 1400, returning the input resistance RL of the pi-network to 1400 ohms, the value of RLP. Thus the plates of the amplifier tubes are unaware of the change in external load impedance.

14. We’ll now make an additional indirect measurement of ROS that proves the conjugate match statement above is true. Leaving the pi-network adjustments undisturbed from the conditions in Step 10, with

the amplifier powered down we again connect a 1400-ohm non-reactive resistor across the input terminals of the pi-network tank circuit and measure impedance ZOS looking rearward into the output terminals of the network. The impedance was found to be ZOS = 18 – j8 ohms.

From a practical viewpoint, measured impedance ZOS = 18 – j8 ohms is the conjugate of load impedance ZLOAD = 17.98 + j8.77, proving that the amplifier is conjugately matched to the load, and also proving the validity of the indirect method in determining that the source impedance of the amplifier is the conjugate of the load impedance when all available power is being delivered to the load.
Thus the data obtained in performing Steps 1 through 14 above proves the following four conditions to be true:

No reflected power incident on the output of the amplifier is absorbed or dissipated in the amplifier, because:

1. The total DC input power is the same whether the amplifier is loaded to match the resistive Z0 load of 50 + j0 ohms, with no reflected power, or to match the complex load of 17.98 – j8.77 ohms with 30.6 watts of reflected power, while 100 w is delivered to either the Z0 load or the re-matched complex load.

2. All the 100 watts of power delivered by the transmitter is absorbed in both the Z0 load and the re-matched complex load cases, with the same DC input power in both cases.

3. All the 30 watts of reflected power has been shown to add to the source power, establishing the total 130 watts of forward power in the case involving the re-matched complex load.

4. All the reflected power is added to the source power by re-reflection from the non-dissipative output source resistance ROS of the amplifier. Had the output source resistance of the amplifier been dissipative the reflected power would have been dissipated there into heat, instead of being re-reflected back into the line and adding to the source power. In addition, the Bird 43 power meter would have indicated 75 watts of forward power, not 95. This proves that reflected power incident on the output of the amplifier does not cause heating of the tube.

It should also be noted, an accepted alternative to the load-variation method for measuring the output impedance of a source of RF power is the indirect method demonstrated above. As performed during the measurements described above, the procedure for this method is to first make the necessary loading adjustments of the output network to ensure that all of the available power is being delivered to the load. Next, the input impedance of the load is measured. It then follows that, as proven above, the source impedance is the conjugate of the input impedance measured at the input of the load, because when all available power is being delivered to the load, this condition conforms to the Conjugate Matching and the Maximum Power-transfer

Theorems17.
Additionally, I previously performed this same measurement procedure using a HeathKit HW-100 transceiver, using several different lengths of coax between the 16.7-ohm load and the output of the transceiver in each of several measurements. The different lengths of coax provided different complex load impedances for the transceiver during each measurement. The same performance as described above resulted with each different load impedance, providing further evidence that a conjugate match exists when the amplifier is delivering all of its available power into its load. These results also prove that the single test with the Kenwood transceiver is not simply a coincidence.

EME operators, who have the greatest need of pattern control, noise temperature and efficiency, would not agree. They use the T match.

Oops. You are talking about just a dipole, so the above doesn't really
apply.

And neither does any worries about skew. If it skews on a dipole who
cares? Just turn it, if you can even tell it skewed.

>50+j0 or thereabouts.

Hi Owen,

Even this Zs = 50+j0 or thereabouts is a distraction. Quite simply,
being able to reject a single value is an evasion of facing the
evidence of source resistance.

What is more comic is both sides couldn't agree more! Truly Kabuki.

>Whilst Walt has documented a quite rigourous experiment, and it produced
>a favourable outcome, it is my view that that in itself is not proof of
>the proposition.

Propositions seem to abound as n+1 the number of participants. I dare
say no two participants can agree what any single proposition is
without adorning further distractions to it like bulbs on a Christmas
tree.

>Whilst one favourable experiment cannot proove the proposition correct,
>just one valid experiment can prove the proposition to be not generally
>true. No doubt the reason for the focus on proving experiments invalid.

Proving a straw man invalid is simple. Proving a murky proposition
invalid is simple too. Unfortunately, the occurrences of actually
stepping up to the bench and showing results other and conclusively
different from those offered is a void in the discussion.

It would seem the qualitative counter-proof comes cheap and that
submitted quantifiables are unchallenged. Quite a paradox.

>If you give some thought to what you could use Zs for, then every valid
>experiment that is designed around that application must produce a
>favourable outcome if Zs is as proposed. If they don't, then the value
>assumed for Zs must be wrong.

>it. The test is documented so that individuals can try it and make their
>own mind up. Some might get favourable results on limited trials... but
>in my view, that is outweighed by unfavourable results from valid

>experiments.

For years I have read that Zs is not ____. Just as quantifiables are brushed off the table of discussion, I have yet to see measure of what the objectors' Zs IS instead under any circumstance that they can conveniently arrange with their own tools and source.

It is a tautology that if it is not X, it must be Y, or Z, or.... None seem to know an explicit answer under any circumstance or configuration of their own gear. Without some value such as 10 Ohms, 50 Ohms, 10,000 Ohms, it leaves a most curious happenstance that any garden variety ham transmitter exhibits either 0 or infinite source resistance - but I dare say no one is going to step forward to accept these boundary limits either!

No counter-proclaimants of ANY value between and including 0 to infinity. It would be a commitment anyone could validate or refute on the basis of science at the bench - and what would follow from that examination? I would find such discussion refreshing in comparison.

What a happy state of ignorance this topic draws out of the wallpaper.

Let's see where the descriptive wave (not a noun) leads us.
Wave-and-go cashcard: contactless payment system.
Wave aquatics: a competitive swim program.
Wave church: "we invite you to be a part of Wave Women."
Wave dash: a technique in Melee that causes a character to slide along
the ground without walking or running.
Wave extension: hair, also called a "fall."
Wave grease: more hair, control pomade.
Wavey gravy: psychedelic sauce.
Wave hook: antenna.
Wave iron: even more hair, for curling.
Wave jumper: a boat.
Wave keyboard: what you type on if you are really kewel.
Wave machine: something one would find at a water park.
Wave meter: a tunable cavity with a frequency scale.
Wave scholarship: The Washington Award for Vocational Excellence.
and probably some more.

Which one is being talked about?

OK, good example. Cataracts presents absortion, transmission and
reflection (they are whitish). To be analog I think should not have
reflection. What do you think? (Perhaps seems maieutics but really I
am trying to put my thoughts in order at first).

What about the third point? I consider it important because light
waves are in three dimensional space, so when they cancels in a
region, reinforces in other and I can understand redistribution, but
line travelling waves are in unidimensional space and here I can not
visualize (realize?) the energy redistribution as in light
interference. Sorry, when I put interrogation words inside
parentheses is that I am not sure the better/adecuated translation.

Let's consider an *ideal* single-frequency laser to be a coherent
monofrequency source for the purposes of discussion.

> 2) What would be Rs optical analog?

I don't know enough about lasers to answer that question. In any case,
I don't think reflections incident upon a laser encounter whatever Rs
that might exist. I think we are going to have to settle for what
happens outside of the laser which in important because what happens
to photons in free space and other mediums cannot be hidden inside a
transmission line. Standing waves of photons cannot stand still in a
coaxial transmission line any better than they can stand still in free
space.

What some people are missing is that visible light waves and RF waves
are exactly the same phenomena, just at a different frequency. The
laws of physics governing light waves also govern RF waves. When
someone says, "RF waves are different from light waves" or "RF waves
can stand still", they are just showing their ignorance. They must
also prove that reflected visible light waves in free space contain no
energy and can stand still or else they are just blowing smoke.

> 3) Superposition is a medium phenomenon ¿yes?, for example "eter".
> Interference an result of it on a other "thing", for example
> photographic plate or screen. Are we agree? K

No, in our context, superposition is the merging of two or more EM
waves in any medium. If the waves are coherent, constructive/
destructive interference can occur. If partial or complete wave
cancellation (permanent destructive interference) occurs, then the
energy in the waves that existed before cancellation must be
redistributed in another direction AND there are only two directions
in an RF transmission line.

I believe that Walter Maxwell defines any reversal in direction of
reflected energy flow in a transmission line to be a "re-reflection".
I prefer to call what happens to a single reflected wave a 1. "re-
reflection" and what happens when two waves cancel a 2.
"redistribution" of reflected energy.

> What about the third point? I consider it important because
> light waves are in three dimensional space, ...

Let's compare coax with 0.2 square inches of cross-sectional area to a laser beam with 0.2 square inches of cross-sectional area. For the same power level, the power density, watts/in^2, will be the same - therefore the Poynting vectors will be the same. With such a concept in place, we can talk about a 100w RF source or a 100w laser source.

well, not quite. they get slower as they move out from the sun. look
at the trajectories of solar wind and how it winds out in a spiral.
if that was the carrier of light it would severely distort our view of
the sun. as it is we can easily see the difference between the speed
of light and the speed of shock waves of plasma (longitudinal waves)
in space... the difference is minutes for light to get here up to days
for plasma waves.

> --
> 73, Cecil, w5dxp.com

Cecil, you are missing a basic point about physics.
Classical physics is seen as factual. All other theorems are
replacement attempts to explain paradoxies provided by classical
physics. When ever one reads the duality theorem it is exactly that, a
theorem which many say is a myth that is being perpetuated, but even
so they declare the wave as a function purely because of mathematical
reasons that the wave function has the same mathematics that can be
traced back to those provided by a particle.
Even so, classical physics holds the major spot in physics where all
other theorems are attempts to topple its position as a collection or
laws or facts.
Maxwell's equations as are equations by Gauss,
Faraday are today considered to be facts that have yet to be
overturned. Tho I call my work a theorem I can just as easily call
them a series of facts which are still accepted to this day. My
findings only uses facts. Classical physics has yet to be dethroned.
The masters were very smart people who were very careful with words
and interpretations of the visibles whereas even today the double
split experiment is torn with missinterpretations in continuation of a
unproven theory
None of the accepted facts that I have used mention the term of waves
and since these laws are part of classical physics I hold to them.
There has not been any theorem that has been expanded to the status of
a law such that classical
physics has been displaced. I am using only what Einstein failed to
locate that which he needed to
further his leanings towards the Standard Model and it was only this
failure that provided a reason to
look for different viewpoints.
If you have reason to displace the legitamacy of Classical Physics as
used by me then state them.

What I have used is short and to the point so I am not presenting a
hardship to whome I consider as a qualified engineer
My best regards
Art

1881. Re: Galvanized or Copper Gound Rods?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-05-28 17:17:28 UTC
From: Irv Finkleman <finkirv@shaw.ca>
Message-ID: <BUSLn.13935$%u7.6015@newsfe14.iad>
Source record: 9581

I used one 10 ft. copper clad steel ground rod and three 10 ft. copper
pipes. The pipes had 1/4 inch holes
drilled randomly throughout the bottom six feet and allowed me to annually
pour an epsom salt solution through them to enhance
ground conductivity. One copper pipe was set about 6 inches away from the
paired copper clad steel -- this
enabled the salt solution to salt the region of both. The two sets were
about ten feet apart and joined together
with heavy copper clad steel wire (Silver soldered). . To one set I attached
a number of random length radials running across the
yard (along two fence lines) and around the side of the house. They gave me
a real good ground as far as I
was concerned. Due to illness I recently sold the house, and extracted the
ground system. Surprisingly there was
little if any degredation of the metal elements -- that was after 27 years
in the ground! Both the copper clad steel
rod and the copper pipes were in good shape. Copper is expensive, but it
lasted a long time and took the
worry about whether I had a good ground away.

To install the copper pipes, I first drove in the copper clad steel rod,
then drew it out of the ground with
a car jack and inserted the copper pipes in the resultant holes.

To make the job easy, I had a young ham use a sledgehammer to drive the
copper clad steel pipe into
the ground and jack it back out -- three times! For the fourth hole I did
not have to extract the rod -- it
was left in place.

I'm no engineer, and never did any ground testing (whatever that involved),
but I was totally satisfied
with the system. Do it once right amd then don't worry about it!

if that was the carrier of light it would severely distort our view of
the sun.

The math for this was done by Stokes before 1850.

>as it is we can easily see the difference between the speed
of light and the speed of shock waves of plasma (longitudinal waves)
in space... the difference is minutes for light to get here up to days
for plasma waves.

The oldest telephone was made from string and cans. We can use the metal
wire.
In the wire can travel the sound waves and the electric waves. The speeds
are also different.
In plasma the ions are the medium for shock waves and the electrons for the
electric waves.

You know almost everything. But you do not know that the teachers are very
nice people who must every year look for new nice students and next look
after them. So they have no time to observe what the scientists and
engineers are doing. They are using the same "pieces to teach".
They started teaching of Copernican's theory 250 years after publication.
So Stokes' aether will be in schools in XXII century.
Do you agree?

Hi Walt,

You understand my "truly kabuki" suitably enough, which means the others must be lurking in the shadows unable to step up to the bench of their own demonstrable scientific commitment.

Your numbers show evidence of source resistance. Like any real resistance, in a complex mix of reactances and phases, all superposition energies collapse to reveal a net value that is either a caloric break-even, gain, or loss. This real resistance is the experience of EVERY correspondent here.

As for your position, your proposal appears to exhibit source resistance where you deny its reality. This is a longstanding difference we have had and I presume will never be bridged.

If you had never opened the door to the conjugate match, because what you argue with your data as support is properly an image-Z match, then you would be on a firmer foundation, rhetorically.

The Z match more close corresponds to the maximum available power transfer theorem and models of Thevenin/Norton sources. Neither of these sources demand a resistor - this was a high school physics artifact with about as much rigor as Sunday school is to theology.

Terman explicitly offers Thï¿½venin's Theorem on the bottom of page 74 continuing onto page 75. He describes the Z match in the middle of page 76. Your argument is what Terman calls an "image-impedance basis." Note the term "basis," it has been my question to you for years as to what basis you have used. I have never gotten an explicit response.

In the second paragraph of 3-8 we find Terman discuss the conjugate basis of matching for maximum available power delivery. I won't belabor what can be read by the multitudes for themselves.

However, beyond this discussion, Terman offers an APPLICATION where its topology is entirely congruent with the propositions being bandied about here. Please turn to pages 262, 263 footnotes to observe plate

resistance and grid-leak resistance being offered - not Zs but Rs.

This last point, yet another distraction, probably brings a collective sigh of relief as the shadows are emptied with those who throng to argue the meaning of resistance instead of measuring it at their own bench.

Truly Kabuki.

Whatever reflects, also absorbs and vice-versa. The notion that the
interface is a singularity (infinitely thin) cannot be found in
reality. Arguments that hinge on this non-existent property are made
for the novice to intermediate student. Those who practice the
science of optics at the bench never observe this metaphor in reality.

Superposition is the collapse of all possible solutions to a real one.
To be real, we must have an observer. Frequently that is called a
load. That load may be a transducer (light cell). Without the
observer, both energies are present - nothing cancels. What is called
redistribution is a superstitious necessity of trying to visualize the
math. Redistribution is a strained term that is useful as a placebo,
but nothing moves in the redistribution (an irony or a paradox which
is more useful in entertainment).

Traveling along the road of using optical metaphors is troubling for
those who have never worked at an optic bench. Cut and paste theory
from eminent authors occludes vision.

Hi Irv,

In fact you had the perfect opportunity to do simple but effective
test through a classic three electrode measurement.

You perform the test three times by rotation among the three
electrodes. You apply a HIGH voltage across the two most distant
electrodes, measure that current, and measure the potential difference
to the third, middle electrode. You must us a high voltage to
overcome local ground currents and any cathodic action. 50 or more
volts is enough.

Hi Cecil and Richard (thanks for answer my questions Cecil, and add
your technical comments Richard).

I reply (is it OK "reply"?) to Richard first because it is part of my
comment to Cecil. Yes, Richard. Tonight I said to me: -the worst term
that you could use, Miguel, was "ether"- :>), because "ether" is a
hipotetical MATERIAL thing, so, as on other material mediums we
usually can literally see interference because interference is
manifested on matter, but we need photographic plates, screens,
retinas, etc. to manifest electromagnetic interference, "loads" as say
Richard, ("observer" it is more sutil and difficult concept, I dare
not with "him").
I needed know what represent that in a line discontinuity (in a load
seems obvious) to better understand Cecil's examples in web page
(http://www.w5dxp.com/energy.htm).
....
Before continue I want to do a comment to know if we agree (more or
less). We partially think with words or symbols, words and symbols
represent concepts or perceptions, concepts are not "out there", as
Einstein said they are: "free creations of human mind". There is not
energy out there, there is not velocity out there, that things are in
our brains (or consciusness if you prefer). We need consensus to
collective think on it, we need "sincrhonize" our minds to
colectivelly think the world...
You think in english, I think in spanish, I need translate "your"
words to "my" words to understand what you say, I can not say: "whats
the hell is a rig!", where are "rigs"! only there are "equipos"
boys! :>) For that I need understand what means Cecil with
redistribution, I belieive I can understand his idea behind the word,
I must make the effort because my own language barrier. Perhaps the
consensus word to it may be not "redistribution", but... what Cecil
tries explain to me? I try never identify the "map" (words, concepts)
with the "territory" (hipotetical real world) because misleading me.
....
Cecil I want to ask you if you are using "photon" term to
methaforically refer to "light". I am not qualified at all to address
this issue in quantic physics terms I thougth we was fully inmersed in
ondulatory theory.

I do not have useful knowledge in laser either. but I can imagine (I believe) the properties of Rs analogy.
I am interested in your optical analogy because analogies often are useful to visualize a new thing knowing old things, it does not matter if we use RF concepts to aproximate optical things or vice versa, analogies are useful crutches (muletas in spanish). Even I agree at our concept that electromagnetic spectrum includes RF waves and ligh waves and they are the same phenomenon, I think that is a result of great insight and efforts of the human mind, it is not so evident. We see light, we sense infrared radiaton, but we can not perceive well RF without instruments (unless we introduce ourselves in a micowave oven or burn with the antenna, of course).
To concentrate light we only need a piece of glass, to do the same on HF RF region we need large wire antenna arrays. Because of this we often need (or employ) very differents models to deal with the "same thing". Probably Maxwell equations solve all of them, but they are difficult ladies to deal :>).
Reconciling optcs models with electric models have its difficulties, but can be productive undoubtedly I believe.

(Richard I do not think wathever reflects also absorbs (ideally at last), It can reflects an transmits but nor absorb, do you agree with it?)

(I do not forget Roy's article, I'm still trying to sort out all the puzzle pieces).

Hello Richard,

I must be honest with you, Richard, for over the years I have often been in a quandary after reading some of your posts--I simply don't comprehent what you're saying in them. I often have to turn to look at some one else and ask " wad't he say? wad't he say?" For example, I don't know what a 'kabuki' is.

You say my numbers show evidence of a source resistance. Then you also say "This real resistance is the
experience of EVERY correspondent here." On the contrary, my understanding is that Keith Dysart and Owen Duffy don't agree with that. Have I misunderstood their posts? Then you say,"What is more comic is both sides couldn't agree more! Truly Kabuki." Again, what is 'kabuki'? In other words, to both sides agree or disagree? Which is it?

In another paragraph you say, "As for your position, your proposal appears to exhibit source resistance where you deny its reality. This is a longstanding difference we have had and I presume will never be bridged." I totally misunderstand that statement, especially a longstanding difference that I didn't know we had. And although my measurements of source impedance (or resistance) indicate their reality, I have never knowingly denied their reality. I can't understand how you could have reasoned that I denied it.

Now we come to the "basis" for my measurements. You state that my measurements appear to be on the basis of image impedances. According to my editions of both Terman and Everitt, 'image' impedances mean that when the generator is connected to the input terminals of the network the impedances looking in both directions at the output terminals of a network are equal. I understand that this can be true if the impedances are purely resistive, but I can't see how this could be true when the impedances are complex, having reactive components. If the impedances in both direction contain equal reactances (not opposite), then delivery of maximum available power cannot be delivered. For the maximum power to be delivered the reactances

looking in opposite directions MUST also be OPPOSITE, describing a conjugate relationship, not an image relationship.

Unfortunately, my editions of Terman must be different from yours, because I find no mention of plate resistance (Rp) or Rs. Rp is a factor in determining the value of RL that appears at the input of a pi-network in an RF power amp, but has no relevancy downstream of the network input, and certainly has no relevance to the formation of a conjugate match at the output of the network.

So Richard, let me get this straight--are you agreeing with my position or disagreeing?

Kabuki?

Walt

Representing, representation, like the term redistribution, are all
crutches for intellect. If you get stuck on one, you are forever
behind. If it works - fine. When the crutch breaks, you have to be
able to walk away without feeling cheated. (Amusing, being able to
walk away means you never needed the crutch in the first place.)

>tries explain to me? I try never identify the "map" (words, concepts)
>with the "territory" (hipotetical real world) because misleading me.

Redistribute is an action verb. Nothing happens until you measure it (you need a load). This speaks to your Ether (or Aether or ï¿½ther) being a medium, but there is no evidence of Ether existing. So for action, it is in the loading - nothing else happens (has action) without a load.

The "concept" of redistribution collapses to zero if you do not take a measure, but it exists if you do? Logically, the causal relationship is with the observation, not with the energy. The load reveals a concept that does not exist without it.

What you wonder about and call a map, or territory, is a forest of loads that give a population of varied responses that are a product of phase differences. Mathematical "representations" of this are called surface maps (your term of map is appropriate) or contour maps. Within these types of representation, you can see patterns. However, the patterns are those revealed by a multitude of loads. Take away the loads and you would see nothing.

>(Richard I do not think wathever reflects also absorbs (ideally at
>last), It can reflects an transmits but nor absorb, do you agree with
>it?)

No. I have measured light at the bench, and I have studied its applications at many scales down to subwavelength dimensions. All materials absorb light without qualification. All materials reflect light without qualification. All materials transmit light without qualification.

You may be tempted to tightly constrain what you call light to force an artificial solution. Do not do it, because that serves no useful purpose.

Consider the sun, light (a photon) from its center has to penetrate its bulk before we see it. It takes something like 10,000 years for that light to reach the surface. Any material you think of here on our mud ball planet is inconsequential in comparison.

Using an optical analogy for RF is very dangerous if you cannot measure it at the bench. Why try to understand two unknowns together?

The greatest danger of an optical analogy is in your perception (I choose that word with care) that IF you are able to "see" it, THEN that means that you "understand" it. Sight is an illusion (another word chosen with care) that is most often clouded by the mind. This topic fills books from both academic and popular writers.

In simple terms, there are optical events that you are certain you can see, but that you cannot measure or show anyone else. There are optical events you and others can measure, but you cannot see.

A simple (but complex one to build) example is the conjugate mirror. It reflects light, but when you look into it, all you see is black. If you have no experience at the bench, then what I write is a puzzle. Although I have described why this happens, I doubt anyone remembers or knows the answer to this contradiction.

If you want a hint, it relates ENTIRELY to your trying to tie together RF, reflection, and other transmission/transmitter topics. Look at the ongoing discussion on source resistance, and note the same word conjugate's appearance in that commentary.

classical physics has been well dethroned by both relativity at the high velocity end and quantum mechanics at the small side of the scale. classical physics does good at 'every day' speeds and for macroscopic things... the types of things that newton and his contemporaries would have been able to experiment with. they could not have known or measured things at very high energies as seen at relativistic speeds, nor could they have measured things at subatomic levels where the 'classical' laws break down.

Hi Walt,

Your confusion is well founded. :-)

Kabuki - Japanese theatre with very elaborate costumes and highly
mannered acting. It is presented in day long plays that many in the
audience feel perfectly at ease with watching, talking to a neighbor,
eating a meal during the performance or taking a break and coming back
to after an hour or so.

Both. However, as to why? They themselves are notably absent from
this discussion. I mark this as a lack of commitment at the bench to
obtain contrary evidence. Perhaps it is casual indifference carefully
woven into passionate and emphatic negations. Such bipolar swings is
what I term as truly Kabuki.

>In another paragraph you say, "As for your position, your proposal

Note your emphasis in the original. It conforms to half the other writers half the time (who can tell with all their mannered elaboration?).

If you can allow that Rp is real resistance, all fine and well. If it takes more than three sentences to state it is not, then that is truly Kabuki. Three sentences may not completely give you enough freedom of expression, but if I see a fire hose response - that is just too much material to justify parsing for a clear answer.

>Now we come to the "basis" for my measurements. You state that my

Well, you have the material at hand. Terman offers succinct meaning. A position is usually in one place. That place is as Terman and NBS writer Stephen Adam (strictly) terms it as "basis." And I asked what basis you use. Please consult the strict usages of the literal word basis (and not the informal understanding of "how") to avoid mixing them. Your pleas are often couched with conjugate basis and you attempt to prove them with image-Z basis. They should not be intermingled.

>If the impedances in both direction contain equal reactances (not

>Unfortunately, my editions of Terman must be different from yours,

You do not have "Electronic and Radio Engineering?"

>So Richard, let me get this straight--are you agreeing with my
>position or disagreeing?

I take no position beyond your data clearly exhibiting the nature of what Terman describes in pages I have referenced. My professional experience has been invested with measuring real resistance to NBS precision and accuracy - this includes plate and collector resistances (albeit at vastly less resolution than standard resistors and such).

Energy creates heat in real resistors. The combination of phases and energies in a resistance still gives rise to heat, if by different degrees that follow phase relationships of all perceived sources. Heat can increase through soaking (a steady elevated current) or through breakdown (the quick flash of an intense voltage arc). These two are very common (even if only on rare occasions) experiences of EVERY correspodent with their own equipment. It is exceptional to deny

this. We have exceptional threads.

Your data does not contradict any of my points - the question is: does your position contradict Terman's discussion and my experience? I have trouble with your mixed basis discussion that clouds my ability to resolve where you stand. Other writers seem to go both ways without any data of their own measurements to inform me about their judgment having authority. Yours is the only data (aside from my own offered earlier in separate discussion) on the table - and it suits me fine.

K1RRR@ARRL posting response by Art Unwin

Are you saying that the laws of Newton, Faraday, Maxwell and Gauss is
now defunct? What should I have used in their place if they were no
good in the areas that I worked with?
Why on earth did NEC work around the equations
of Maxwell when they had been toppled? I used Newton,Faraday,Maxwell
and Gauss's laws only.
Who and what has replaced them in the areas where I mistakenly used
them. Did Ohms laws
survive this onslaught and who got the award from Oslo? I would like
to have another stab at my work
using the data that has replaced them, so I could do with some
guidance from you so my work is not wasted again. Do you know what the
replacement antenna computer programs will be based upon and are any
presently available on the market?
Thanks for the update. Why not share what you have with QST so your
fellow hams may benefit
from the up to dated textbooks now supplied to the new generation in
Universities. I heard that Texas
is redoing all the school textbooks but I didn't realize that
education had taken such a radical change. And of course as science is
changed in Texas so goes the whole Country. On another thought, will
degrees obtained before this update be grandfathered in?
My very best regards
Art Unwin

Richard, I'm still trying to assimilate all the info you presented in you post above. So please allow me to skate around a bit.

First, concerning plate resistance, Rp. This may be where we don't understand each other. My position on Rp is that it is a non-dissipative resistance, and can be measured by noting the change in Ip with a change in ep with grid voltage held constant. The result of the effect of Rp is thus one of inverse feedback when the Ip is varying with respect to a change in grid voltage that causes a change in Ip that is inversely related to the change in ep appearing across the plate load resistance with the plate source voltage held constant. Rp thus is not relevant to the source resistance of an RF power amplifier other than its effect on RL looking upstream of the input to the pi-network. When I speak of the source resistance (or impedance) of the RF power amp I'm referring to the resistance (or impedance) appearing at the output terminals of the network, which has nothing to do with Rp. If you're considering Rp as the source resistance that's probably the reason for our disagreement, and if you do consider Rp as the source resistance I believe you're wrong.

And concerning the basis for the impedance matching, I don't consider that I'm comingling image impedance with conjugate impedance. I simply can't construe Terman's definition of 'image' impedance as relating to the procedure I used in measuring the source impedance appearing at the output of the network. This is because Terman says the image impedance at the output terminals of the network is the same looking in both directions. This condition cannot occur when the reactance component in the load is the opposite to that looking rearward into the network, a condition required to satisfy the Maximum Power Transfer Theorem with respect to delivering all the available power.

However, I will say this, I appreciate your statement that my data suits you fine.

Walt

Hi Walt,

Thank you for the restrained answer. Yes, we do not agree here.

To the matter of the conjugate basis. Terman quite distinctly gives us a real R that remains after the cancellation of reactances. As a hallmark of first principles, it is very clear and concise. The source R must match the load R for the source to deliver the maximum available power. By the same hallmark, this too is very explicit. Terman calls this R (the remnant of conjugation) in the source: "the resistance component of the generator impedance."

For you and others to say what the source is "not," that is not a solution for what the source "is." This is what I speak of when you ask if your critics agree or disagree. You stand with your critics against the testimony of your data that stands with Terman.

The plate resistance can be described physically to suit any objection that I have so far heard from the community. It suits very few who embrace thought experiments that have never warmed a bench nor flickered a measurement instrument. The collapse of rhetoric has exposed the vacuum of counter argument.

>However, I will say this, I appreciate your statement that my data
>suits you fine.

Walt, your methods are first methods. Your care for propriety exceeds all bold statements that carelessly condemn you. Your achievements give you the status of not having to endure taunts and endless bickering. Your steadfast self examination and willingness to sit at the bench is the rock of faith in what Hams aspire for in engineering. As for your humanity, I find you a proud father and loving husband. I think of you in no other terms, even when my prose is dense or obtuse, and my engineering demands are harsh and pointed.

If my allusions to Kabuki are obscure, it is through my upbringing living in Japan as a tyke. If I might balance that obscure reference

for one that is more to my tone here, I call you Sensei - a master of learning and teaching.

Hi Richard.

Really brilliant and good arguments, it is a pleasure for me to read them. In certain dialog level I can agree with almost all of it (I said I am interested in knowledge theory or science philosophy) but, you know, they are philosophical and controversial topics. Reality, duality, consciousness, observer...
In technics we are (or use) a much more naive vison of world and It works!, there is not strange Schrödinger cats in ham radio! (or in radio technics) :>)

Models Richard, all are models, mathematical models, physical models, naive models, "Ideas", representations of "reality" in our minds. We, humans, walk with our crutches -always- => simple crutches, elaborated crutches, little crutches, BIG crutches... :>)
All of my physics and electronics books have "representations", thousands of them, why not? they work...! -except when don't work :>(- Well...when not work => chao with electron "little balls", chao with clasical electrodynamics, chao with Newton's laws, chao with Reality!, It is good for me... very exciting!

I understand what you say Richard but also I think that you seems (to me) adscribe to a sort of, "right model" or "true model", I'm not, I am a little exceptical about "truths" o "rigth sciences", for that reason I like listen as carefully as I can, others ideas. Listen, this

not a criticism to you, remember I said "In certain level of dialog I can agree..."

The bench... all of my life spent on the bench. The bench it is a good friend, -probably an essential friend- but tends to be a fa little "gross" friend. We need also a rational friend (and -why not- an intuitive friend) to make a bingo. With "rational" friend we have, mathematics, calculus, idealized models,:real world is: this tree, that tree, it is not easy (for not tell impossible) to understand a world of individual trees. Rational friend invents the "ideal tree" (certainly not a "bench tree") and works...! we can operate very well with ideal trees!, we can put them into simbolic equations, inside computer memories, good thing (for me) ideal things, total reflection, full transparent thinghs, cuasi-infinitely thin things.

Yes, analogies are dangerous, I know, women too... I dare to risk :>D

> It reflects light, but when you look into it, all you see is black.

Very interesting thing, I like to see one (better if I can understand it)

Richard, I feel that I must to return to Ham radio world and try to see if it is possible compatibilize my old Terman model with yours. This dialog does not bother me at all, as I said It is a pleasure, but without wanting, I am going out off topic :>) I truly enjoyed your comments.

73

Miguel

PS: Certainly I did not postulate the existence of an ether, here we usually call it figuratively, like an old friend, as a kind of "Santa Claus".

You know almost all but only almost.

There are many aethers. One of them was Lorentz' aether in form of
motionless solid body. No such without any doubts. So it is obvious that it
is debunked.

You know that the Sun rotate together with the plasma and the dust. The
plasma and the dust is the Stokes' aether.
In that time another scientist Ludvig Lorenz was sure that in space is
enough matter to propagate the waves.
Both of them did not know that the electron exist.

Teachers could not stay up to date because the all is the top secret.

You can't see it! That is the point. It is also by definition. To
understand it, you have to understand the conjugate match. Have you
been following that story with Walt and myself?

Like I said, trying to learn two things at the same time, when you
cannot understand either of them singly, is foolish. Metaphors (RF as
photon theory) often fail at the wrong time without being noticed.

Probably, but the real answer is that the performance will be different.
You'll need to try it out. The T-feed might actually be quite good on
the lower frequencies - especially 80m - for long-distance contacts. But
you will need a good ground or counterpoise system. Ideally, your
counterpoise should be around a quarterwave (for all the bands where you
use the antenna as a T), so, if it looks promising, you might like to
try multiple wires.

The main problem with any endfed antenna, when fed directly in the
shack, is that you will have a lot of RF in the shack - and you will
also pick up more 'domestic' QRM and hash, usually from things like
switchmode power supplies and all the other 'non-amateur-friendly'
equipment deemed essential for modern-day living.

fortunately maxwell's equations work just fine for macroscopic stuff like hams use, so you are still ok with those. when someone writes an antenna program that uses qed you might want to upgrade though. and newton still works for most cases you will ever run into, though it would fail to explain some effects if you carried an atomic clock on a high speed jet or tried to orbit your own satellite. Ohm's law is still fine for anything you will do also, unless you really tried to get into superconductive antennas, then you might have some problems.

The first guesses at the nature of the ether were obviously wrong. But we now know that if you replace the word "ether" with "quantum soup" in your statements about ether, that you will be technically correct as far as quantum physics can determine. Take a look at the Casimir Effect to see if empty space is really empty. In reality, totally empty space would be outside of the space/time of the known universe.

http://www.answers.com/topic/casimir-effect

> I needed know what represent that in a line discontinuity (in a load
> seems obvious) to better understand Cecil's examples in web page
> (http://www.w5dxp.com/energy.htm).

At the junction of two transmission lines, if the characteristic impedances (Z01 and Z02) are not the same value, then reflections and subsequent interference will usually occur. This is similar to saying: At the junction of two light mediums, if the index of refraction is not the same value in both mediums, then reflections will occur from a (laser) light beam normal to the two surfaces. I am specifying normal=90 deg. and ignoring refraction which is of little importance in an RF transmission line.

And Shakespeare said:

"What's in a name? that which we call a rose
By any other name would smell as sweet; ..."

There's not much argument between the definition of "rose" and "rosal". I call that a 1st level abstraction. Things get a little more complicated at the Nth level abstraction. If in Texan I said, "Ah reckon Ah'm gonna amble over yonder directly", you might have trouble with the meaning (except for "amble". :-)

> Cecil I want to ask you if you are using "photon" term to
> methaforically refer to "light".

No, EM (light and RF) waves are known to be quantized and therefore consist of photons. The reason that I refer to the photons is that photons must obey a certain set of laws of physics. For instance, they must move at the speed of light in a medium. Photons cannot stand still in a standing wave. Therefore, any theory of physics that requires photons to stand still is incorrect. That would include the particular interpretation of the lumped-impedance model that some folks are pushing here on this newsgroup. The only time I will refer to photons is when the presented EM wave theory contradicts the accepted laws of quantum physics. It is simply an attempt at trying to keep some folks honest.

The point is that what we see at visible light frequencies also happens at RF frequencies but we cannot see RF. By switching to a visible light example, I can point out the errors of someone attempting to pull the wool over the eyes of the unwashed masses.

> (I do not forget Roy's article, I'm still trying to sort out all the
> puzzle pieces).

Note that Roy seems to be completely ignorant of this fact of physics: "... the photons are redistributed to regions that permit constructive interference ..." as described on the Florida State web page at the bottom of the page:

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

In an RF transmission line, the only "regions that permit constructive interference" is the single opposite direction in the transmission line from the direction of destructive interference. In the absence of a localized source of energy, any destructive interference in one direction (at an isolated impedance discontinuity in a transmission line) must be balanced by an equal magnitude of constructive interference in the opposite direction. The conservation of energy theorem will have it no other way.

If you are familiar with the scattering parameter/matrix equations, much can be learned by analyzing them. Note that the equations are phasor math, not simple algebra equations.

http://www.sss-mag.com/pdf/hpan95-1.pdf

b1 = s11*a1 + s12*a2

b1, the total reflected voltage toward the load, is equal to the forward voltage (from the source) reflected from the impedance discontinuity, phasor added to the transmitted reflected voltage through the impedance discontinuity (from the load).

b2 = s21*a1 + s22*a2

The total forward voltage toward the load, is equal to the transmitted forward voltage through the impedance discontinuity (from the source), phasor added to the reflected voltage (from the load) that is re-reflected back toward the load by the impedance discontinuity.

The a and b parameters are voltages normalized to the square root of Z0. Squaring both sides of each equation will yield the interference terms in watts, that indicate where the energy goes, i.e. which of two directions in a transmission line.

Note that if b1 = 0, there is (by definition) total destructive interference between s11*a1 and s12*a2, i.e. the same as a Z0-match in a transmission line.

Even if no classic reflections (associated with a physical reflection coefficient) exist, as in Roy's foot-for-thought example, destructive interference at the source resistor will cause some or all of the energy in the reflected wave to be *redistributed* (redirected) back toward the load as constructive interference. Since the wave cancellation causes a reversal in direction of reflected energy (somewhat resembling a reflection) Walter Maxwell, in "Reflections" defines that reversal as a "reflection from a virtual short". Presumably the virtual short (or open) concept would also apply to a 1/4WL thin-film coating on non-reflective glass.

Miguel, "redistribute" is not in my Spanish/English dictionary but "redirect" is and might be a reasonable mental substitute for you to conceptualize. From the FSU web page, ...the photons are redistributed (i.e. redirected) to regions that permit constructive interference ... .

Hi Richard,

I sincerely appreciate your kind words concerning my humanity, and I'm proud to have you call me Sensei. I have always somehow doubted your feelings for me as a person, but your words above have relieved that feeling, Thank you.

As for our disagreement on image matching, I remember reading many years ago in books concerning networks involving telephone circuits that dealt only with resistive terminations. Those readings did specify that with image resistances the resistances were the same in both directions. Nothing was said in those books concerning reactance in the circuitry. Apparently we have different editions of Terman. Mine doesn't discuss R as the remnant of conjugation, so if only R is considered in the image impedance I can concur with you on this issue.

I also want to be clear on my position concerning plate resistance Rp as the source resistance of the RF power amplifier. My position is that it is not. I do understand that Rp is a factor in determining the value of RL that appears at the input of the tank circuit, but not the source of power delivered at the output of the tank circuit. Rp is a non-dissipative resistance, not a resisTOR with physical characteristics. I consider the voltage-current ratio R appearing at the output of the tank circuit to be the source resistance of the RF power amplifier. If you do not agree with this position then I guess we'll just have to agree to disagree, unless you can find some way to change my mind.

I thank you again, Richard, for your kind words.

Walt

>
>I am interested in your optical analogy because analogies often are useful to visualize a new thing knowing old things, it does not matter if we use RF concepts to aproximate optical things or vice versa, analogies are useful crutches (muletas in spanish). Even I agree at our concept that electromagnetic spectrum includes RF waves and ligh waves and they are the same phenomenon, I think that is a result of great insight and efforts of the human mind, it is not so evident. We see light, we sense infrared radiaton, but we can not perceive well RF without instruments (unless we introduce ourselves in a micowave oven or burn with the antenna, of course).
To concentrate light we only need a piece of glass, to do the same on HF RF region we need large wire antenna arrays. Because of this we often need (or employ) very differents models to deal with the "same thing". Probably Maxwell equations solve all of them, but they are difficult ladies to deal :>).

Maxwell equations are wrote by Heaviside.

>Reconciling optcs models with electric models have its difficulties, but can be productive undoubtedly I believe.

Now light is produced with the electric device:
"As the electrons are undergoing acceleration they radiate electromagnetic energy in their flight direction, and as they interact with the light already emitted, photons along its line are emitted in phase, resulting in a "laser-like" monocromatic and coherent beam. The mirrors show in the sketch below are superfluous, as all the light is emitted in one direction anyway."
From: http://en.wikipedia.org/wiki/Halbach_array

When electrons oscillate they disturb the "electron see" and that are waves.
To achive the oscillations we use different devices.
The Halbach array is for light. The dipole for RF. For radar and microwaves the another.

Hi Walt,

Go to the index and look up Thï¿½venin. The material should be found in
two areas:
1. Circuits with Lumped Constants - Thï¿½venin's Theorem - Impedance
Matching
2. Audio Voltage Amplifiers - Resistance-coupled Amplifiers

>
>> In this condition the DC plate voltage is 800 v and plate
>>current is 260 ma. DC input power is therefore 800 v ? 0.26 a = 208 w.

I will be concerned with nothing else outside of this specification as
this is a discussion of the "real" Tube, and a power supply which will
be considered as loss-less.

First. There is one current loop throughout the entire system.

Second. Unique to a tube path within that current loop, there are two
characteristic current types. These are the convection current WITHIN
the cathode-plate interval, and the induction current that completes
the loop from plate to cathode through conventional power supply
wiring.

Third. The induction current's mobile electrons move at a rate of
meters per minute; whereas the charge mobility is near light speed.

Fourth. The convection current's mobile electrons (a literal particle
stream in a vacuum) move at a rate of near light speed. The term
"near light speed," in this case, is limited by the plate potential of
800V and can be computed; whereas the charge mobility is near light

speed, but generally higher (and specifically higher for 800V) than the electron speed.

Fifth. It takes work to move an electron initially at rest to near light speed over the interval between the cathode and the plate with nanoseconds transit times.

Sixth. The electron gains kinetic energy from the field between the plate and cathode.

Seventh. The kinetic energy of the electron is converted into heat upon striking the plate, the heat energy being equal to the power supply energy expended in accelerating the electron.

I will forgo the math of how considerable the resistance, power, and heat is. All can be found from the data quoted above. Clearly, the plate resistance is real in every sense of the word. It is the limiting factor of the current path hence it is the source resistance in every sense of the word.

The seven points I enumerate are from material drawn from a single source. I am sending you the full chapter treatment that speaks to this topic alone from:
"Physical Electronics," Curtis L. Hemenway, Richard W. Henry, Martin Caulton; John Wiley and Sons, 1962.

Others may ask for copies of this reference. Others may ask where the heat comes from, a topic I would enjoy elaborating upon. It is a very simple explanation that by using Walt's data above, can be rendered into Watts/Temperature with only the difficulty of pressing calculator keys. These values than can weighed against real and tested observation at the bench of the same tube in operation.

I cannot imagine anything else meriting discussion.

I all

Richard, I can not translate "Is yours dead?", I suppose means
something as "if it is my last word about it". Well...I do not believe

in witches but there are, there are! I shall not bet :>)

> Have you been following that story with Walt and myself?
Sorry, no. ocassionally I read the topic in this newsgroup long time ago.
....
I agree Cecil, be indulgent with my poor translations, I should have written "I don not postulate Ether, without 'an' before", pointing - with the capital "L"- to our old friend "luminiferous ether"; quantic ether it is a different and very interesting stuff, isn't it?
I can not tranlate your Texan sentence, is a dialect? (patois?). Would you mind write it in basic "english for aliens" for me).
I do not quite understand this => "Photons cannot stand still in a standing wave." -You do not ascribe to wave-particle duality notion?-

As I understand quantic numbers of HF energy are a such extremely small quantities that have unmeasurable effects, I understood (or suppose) you wanted mean quantic physics born of fail of classical electrodynamics to explain all phenomena.
When I pointed to dimensions of transmission line space vs tridimensional space I am thinking of what you called (named?) "redistribution" as meaning the only possible solution in such space is redirection (or reflection). Is it OK?
From me understanding "reflection" is a way of "redirection" of light that obey to the reflection law of optics, in transmission line space I think would be synonymous (at last in spanish language). Do not you agree?
Anyway, I think that classic physics is enough to explain phenomena on extremly low quantic number systems, as HF energy or cars in movement :>)

Returning to analogy. I can not realize how associate Zc changes to refraction because I learnt refraction as a differente speed of light medium phenomenom. Give me a hand.

["re" it is only a prefix, look for "distribute" (or verb "distribuir" in spanish => "Give something its timely placement or convenient location". I bet it has same meaning in english]

Before advance more. I am not yet quite discern your (plural) conceptual differences. Please remember that I did a question and you answer with concepts of advanced stages of your discussion. Until now - seems to me- Owen sustain our clasic Terman et al teachings and is critic of Walter's theory; you too but from different point of view (redistribution of energy, interference, photon laws, etc). I do not know yet Roy's differences, and Richard would support all Walter's hipothesis.

Also seems to me that a piece of discussion revolves around "truthness" (in weak sense of word) of respective models more than capacity of each one to give correct results to empiric measurements. Perhaps a little summary of coincidences and differences can serve to

other readers, and me, obviously :>)

73 and good weekend to all

It was a Quantum joke. It has groans AND laughs until you read it.

>> Have you been following that story with Walt and myself?
>Sorry, no. ocassionally I read the topic in this newsgroup long time
>ago.

Too bad. I find plate resistance an interesting application of macro
and micro action. I thought you would too.

>"Photons cannot stand still in a
>standing wave."

Gad, what an awful statement.

>As I understand quantic numbers of HF energy are a such extremely
>small quantities that have unmeasurable effects,

They are measured. Your "understanding" is an example of how a
metaphor can throw you into the ditch. Trying to go down the optical
path to discuss RF will find you walking in the bushes.

>Zc changes to
>refraction

Gad, another awful statement.

>["re" it is only a prefix, look for "distribute" (or verb "distribuir"
>in spanish => "Give something its timely placement or convenient
>location". I bet it has same meaning in english]

Your English is fine.

>Richard would support all Walter's
>hipothesis.

No, I don't support Walt's hypothesis, I support his data. Walt and I
disagree about Plate resistance being "real." It is a very small step
over a very large boulder. (Quantum tunneling would make it easier.)

The "problem" with Plate resistance seems to have arrived through
creationism - a novel superstition instead of a simple superposition.

>Also seems to me that a piece of discussion revolves around
>"truthness" (in weak sense of word) of respective models more than
>capacity of each one to give correct results to empiric measurements.

>other readers, and me, obviously :>)

The word you are trying to find is "validity," that is, if this is a scientific issue. You are right about "truthfulness" if it is a religious issue. Or possibly a boolean logical result if we left the realm of analog.

Validity is a result of testing results (scientific method) against expectations.

Truth is a result of burning someone (auto de fï¿½) until they agree with you.

Choose your company with care. Do they work at the bench, or do they play with matches? :-)

Hi Richard,

Thank you for sending the copy of the paper you referenced. I've been reviewing it this afternoon. Although I understand that induced current results from a moving charge, I'm not as comfortable discussing the Rp issue in terms of charges as I am with currents, so I'm having a little difficulty in coming to grips with Rp while reviewing the paper. Consequently, I need a little more time assimilating the info before replying further in hope of resolving our difference on the subject.

I'll be back with you as soon as I'm ready.

Walt

Looks like my follow up post didn't make it through.

Richard I intend these three ground rods to be the start of grounding my station, not as a counterpoise for one of my antennas. These will be bonded to my radios and the electrical service entrance ground.

Why do you say this does not make an RF ground?

Thanks, Bob

Hi Bob,

If by "this" you mean the three rods, then they will NOT make an RF
ground.

Of necessity due to wavelength, your ground must be spread out (not
buried) to one quarter wavelength. For 160M, your radials (not ground
rods), should extend 40 meters from your radiator.

Classically, you would need 120 radials for an RF ground.

Classicism and practical reality diverge, so there are variations on
all of this EXCEPT ground rods do not make an RF ground.

Miguel, your English is a magnitude better than my Spanish so don't
worry about it. "Quantum ether" are two words that I have never seen
together before. Maybe you will be famous for that concept.

> I can not tranlate your Texan sentence, is a dialect? (patois?). Would
> you mind write it in basic "english for aliens" for me).

Northern Americans cannot understand it either. :-) The translation
is: "I think I will walk over there after awhile." The Texan word
"amble" came from the Spanish word "amblar".

> I do not quite understand this => "Photons cannot stand still in a
> standing wave." -You do not ascribe to wave-particle duality notion?-

Some of the RF gurus will try to convince you that the energy in RF
standing waves is standing still. But since those RF waves consist of
photons which must necessarily move at the speed of light in the
medium, they are dead wrong. The correct concept is that a pure
standing wave doesn't transfer any *net* energy but the two equal
component traveling waves, forward and reverse, are still moving at
the speed of light in opposite.

> As I understand quantic numbers of HF energy are a such extremely
> small quantities that have unmeasurable effects, I understood (or
> suppose) you wanted mean quantic physics born of fail of classical
> electrodynamics to explain all phenomena.

The point is that the photonic energy in an RF wave cannot stand
still. That defeats the argument that reflected waves don't exist or
don't contain any energy. Such is simply nonsense.

> When I pointed to dimensions of transmission line space vs
> tridimensional space I am thinking of what you called (named?)
> "redistribution" as meaning the only possible solution in such space
> is redirection (or reflection). Is it OK?

Light waves can be reflected, refracted, and/or redistributed in any
3D direction. RF waves in a transmission line can only flow in two
directions, forward and reverse. That simplifies things considerably.
Coherent waves flowing in the same direction in a transmission line
suffer permanent interaction.

> From me understanding "reflection" is a way of "redirection" of light
> that obey to the reflection law of optics, in transmission line space
> I think would be synonymous (at last in spanish language). Do not you
> agree?

Yes, but wave cancellation accompanied by destructive interference can
also redirect EM energy. Wave cancellation is what w7el is missing in
his food-for-thought article.

> Anyway, I think that classic physics is enough to explain phenomena on
> extremly low quantic number systems, as HF energy or cars in
> movement :>)

Yes, but when classic physics allegedly doesn't obey the laws of
quantum electrodynamics, something is wrong, and quantum
electrodynamics wins every time.

> Returning to analogy. I can not realize how associate Zc changes to
> refraction because I learnt refraction as a differente speed of light
> medium phenomenom. Give me a hand.

For the purposes of RF waves in a transmission line, you can forget
refraction as an irrelevant effect.

> ["re" it is only a prefix, look for "distribute" (or verb "distribuir"
> in spanish => "Give something its timely placement or convenient
> location". I bet it has same meaning in english]

Yes, that is probably correct.

> ... you too but from different point of view
> (redistribution of energy, interference, photon laws, etc).

My concepts are directly from the field of optical physics. You might
want to obtain a copy of "Optics", by Hecht. It is available in
Spanish:

http://www.astronomyinspanish.org/slm/eng/book/coll/optica_hecht

This book will teach you more about EM *energy flow* than any RF
engineering book that I know of.

> Perhaps a little summary of coincidences and differences can serve to
> other readers, and me, obviously :>)

The model that w7el uses for his food-for-thought article on forward
and reflected power is obviously wrong because it doesn't indicate
where the reflected energy goes. When a model confuses the user and
obviously doesn't represent reality, it's time to upgrade to a better
model. The EM wave model used in optics does necessarily track the
reflected energy because optical physicists cannot easily measure
voltage.

>reviewing the paper.

Hi All,

For others, there might be wonder at the meaning of induced or inducted current - or convection current for that matter. It would be useful to expand here in a new thread.

First. In the interval between cathode and plate, there are only electrons. In other words, there are no conductors as are found everywhere else.

Second. When an electron flows between the cathode and the plate, charge is moving. By convention, this is called current. It goes by a special label - convection current.

Third. The interval between the cathode and plate is part of a complete circuit that travels through the power supply, returns to ground and rises from ground to come to the cathode.

Fourth. For charge movement through the interval between cathode and plate, there is exactly the same charge movement through ALL wiring connecting the plate to the power supply, wiring from the power supply to ground, and wiring from the ground to the cathode.

Fifth. The charge movement throughout the wired circuit, by convention is called current. it goes by a special label - induced current.

The distinction between induced current and convection current is found in their transport media. One is metal, the other is vacuum. The convection (like convection heat) is electron movement in space which induces current in the wire. This induction is NOT like transformer induction. It has absolutely nothing to do with magnetic linkage. We could call it induction if the entire circuit were composed of wire. That is, the movement of one electron "induces" the movement of another electron.

Similarly (and tipping my hand about reflected waves), an extra electron push in the wiring will induce an electron in the tube to move. The current is inextricably locked in a dynamic flow. There is

no new physics in this anywhere.

So why two terms? The necessity of this seemingly obscure point is to exhibit how heat is formed, and why the plate of the tube is a literal, real resistor in this circuit. Very few correspondents (read none but myself) to this board dwell on this, and they end up dismissing the real resistance of this specific and consequential source as a mathematical fiction suitable for only milliwatt signal generators.

Hi to all...

Richard, do you agree with Walter's theory on "Another look at reflections" in reflections topic -out of plate resistance differences-?

> The word you are trying to find is "validity,"

No, it was more near of your second => "Truth", or "The Truth", the metaphysical "truth" :>)

> Walt and I disagree about Plate resistance being "real"

What is "real" for you? For me it is a slippery word ever ready to disputes, in knowledge matters makes us think of the "thing itself" and with it, we quickly fall into endless scholastic discussions. With models "the thing" it is a little more ease, models only must be internal and measurements consistent. Models are neither "True" nor "Real", they are modestly "valid" :>) What do you think?
....
I believe I am in a privileged position because my english weakness : when I am about to disagree with you, I tell me -"probably you do not translate well, Miguel, ask again"- and when you answer to me then voilá! I do not disagree... Viceversa, perhaps language give me a second chance with you because you are more forgiving with me :>)

Example:
Miguel =>
> I do not quite understand this => "Photons cannot stand still in a
> standing wave." -You do not ascribe to wave-particle duality notion?-
Cecil =>
> Some of the RF gurus will try to convince you that the energy in RF
> standing waves is standing still. But since those RF waves consist of
> photons which must necessarily move at the speed of light in the
> medium,

So, now I believe what he is trying to tell me is stationary wave is a measured time dependent magnitude resulting of two near speed of light traveling waves, manifestating in our measurement apparatus (observer or "load" as said Richard)... It is good to me.. Then, I do not care anymore the ugly (nasty?) word "photon" :>), and finally to my joy, next Cecil sentence confirms my translation/interpretation!.

> Coherent waves flowing in the same direction in a transmission line
> suffer permanent interaction.

It is difficult to me reconcile superposition principle with "interaction", because in spanish "interacción" word means: "Action exerted MUTUALLY between two or more objects, agents, forces, functions, etc" (capitals are mine) And I learnt two or more electromagnetic waves can pass one through other by same point of the SPACE without recognizing themselves (unlike particles that "collide"), then, by definition, they not interactuate themselves at all.
We do not "see" any standing wave in space when two same path opposite direction RF rays cross themselves and there is not contradiction. Are you agree?
In transmission lines instead it is not easy to think that because more "tangible" standing wave voltages and currents make us think they are "interacting". What do you think about it?,

> but wave cancellation accompanied by destructive interference can
also redirect EM energy

To satisfy the energy conservation principle, isn' it? This produces a reflection, right?

> but when classic physics allegedly doesn't obey the laws of
quantum electrodynamics, something is wrong, and quantum
electrodynamics wins every time.

Could be classic electrodynamics be right but we are not applying correctly, and then classic model not become a losser in this matter?

I see you do not agree with some Roy Lewallen proposition: do you agree with Walter Maxwell on this topic?

Sorry (for me) Cecil "quantum ether" is not mine :>(

Thanks for optics book recommendation.

You have the second privilege of understanding a confused statement
when you see it. This is language independent.

>We do not "see" any standing wave in space when two same path opposite
>direction RF rays cross themselves and there is not contradiction. Are
>you agree?

To see is to witness, or be an observer (from the Latin observare, ob-
over, -servare watch). When two light waves illuminate the same load,
and the load is observable, you see the combination of two energies at
that load.

A standing wave does not exist until you measure the combination of
the contributions at a point. You can, of course, populate a large
area with many point-loads if you wish to map a region. Under very

controlled circumstances, you will get to see a nice pattern.

The sport is found here: Of course, you could see the same pattern at the same points by the projection of an image upon them from one source.

Could you tell the difference between (1) that single source projected image and (2) the standing wave combination of several sources?

This is too much fun already, but.....

So, for Truth: Is a movie projector acted upon by the movie it projects? Was your camera happy because your photograph shows a smile? The Truth would say yes. What would Schrodinger see?

Does that help?

>In transmission lines instead it is not easy to think that because
>more "tangible" standing wave voltages and currents make us think they
>are "interacting". What do you think about it?,

A confused statement.

>> but wave cancellation accompanied by destructive interference can

>
>Could be classic electrodynamics be right but we are not applying
>correctly, and then classic model not become a losser in this matter?

Let's see now. You have three things to figure out. RF, Light, and QED. I hestitate to wonder what could possibly follow if you prove to be to slow to figure these out. Perhaps sudoko patterns revealing the entanglement of strange attractors. (Sorry for the translation overload.)

And this started with Truth? :-)

Write when you receive more inspiration. (A supernatural divine influence on the prophets, apostles, or sacred writers, by which they were qualified to communicate moral or religious truth with authority; a supernatural influence which qualifies men to receive and communicate divine truth; also, the truth communicated.)

When a model confuses the user and obviously doesn't represent reality, it's time to upgrade to a better model. The EM wave model used in optics does necessarily track the reflected energy because optical physicists cannot easily measure voltage.

The intensity is also accurate.
The end of the dipole reflect and transmit. The proportion is measured as VWSR.
But for this you need the Electric Wave Model.
EM was stripped away by Royal Society in 1864.

Mr. S... please, you need to do 2 things... first, get a better
newsgroup editor or use the groups.google.com web site to post
replies, whatever you are using now messes up the indentation for
quoted text and makes it impossible to figure out what you wrote and
what is quoted. second, keep your 150 year old theories in threads
where they belong, they will only cause confusion to those who are
trying to discuss modern methods.

does it really matter what the mechanism of generating the heat is?
the fact that there is heat generated in the plate means there is
energy lost from the electrons, be it due to impinging on the plate
mechanically or due to the metal resistance it is still a loss of
energy. And since there is more heat when there is more plate current
we can model it as a real resistance. The only question is then, is
it linear or not. that should be a 'relatively' simple measurement,
and one that has likely been done by a researcher somewhere along the
line.

What you learned is usually true in free space. Two light waves can pass through each other at the same point in space without affecting or interacting with each other because they are *not collinear*. It is very difficult to align two light beams in free space such that they are collinear. However, it can be done in an interferometer.

http://www.teachspin.com/instruments/moderni/experiments.shtml

But in an RF transmission line, please understand that there is *no way to keep the RF waves from being collinear* since it is primarily a one-dimensional space with only two possible directions. Therefore, any two coherent RF waves traveling in the same direction in an RF transmission line, will interact and have a permanent effect. For pure sinusoidal waves, the transmitted wave, the re-reflected wave, and the constructive interference wave are all coherent and collinear and merge into a single forward wave flowing toward the load. The component waves become inseparable.

> We do not "see" any standing wave in space when two same path opposite
> direction RF rays cross themselves and there is not contradiction. Are
> you agree?

Eugene Hecht, in "Optics", describes standing waves of visible light in free space. I'm not sure that humans can "see" the standing wave detail because the frequency is so high, but standing waves of visible light can certainly exist in free space. If you can, please obtain a copy of "Optics". If one routed a standing-wave of light through a cloud chamber, it would become visible. I don't know if the human eye can resolve the high and low interference patterns but I'm sure instruments could detect it.

> In transmission lines instead it is not easy to think that because
> more "tangible" standing wave voltages and currents make us think they
> are "interacting". What do you think about it?,

Coherent collinear waves traveling the same direction in a
transmission line superpose, merge, and interact. This invariably
occurs at an impedance discontinuity point during interference
immediately after normal reflections have taken place. RF waves
traveling in opposite directions in a transmission line with a
constant Z0, do not interact.

> To satisfy the energy conservation principle, isn' it? This produces a
> reflection, right?

Walter Maxwell defines it as a reflection. I am a little more careful
and have adopted the following standards from optical physics. A
"reflection" is something that happens to a single wave and
corresponds to a physical reflection coefficient. A "redistribution"
can be a reflection but can also involve interference between two or
more waves. If superposition is involved, I use the word
"redistribution" rather than "reflection". Walt lumps the concepts of
normal reflection with wave cancellation and introduces the concept of
a virtual reflection coefficient. Both approaches work. IMO, mine is
slightly more detailed. In "Reflections", under the 1/4WL matching
stub section, Walt proves that he fully understands the role of
constructive/destructive interference in the redistribution of energy.

> Could be classic electrodynamics be right but we are not applying
> correctly, and then classic model not become a losser in this matter?

Yes, if w7el would recognize the energy content (V^2/Z0 watts) that
exists in the voltages that he is superposing, he would be able to
track the reflected energy from the load back to the source and then
back to the load as a component of forward power.

> I see you do not agree with some Roy Lewallen proposition: do you
> agree with Walter Maxwell on this topic?

In his food-for-thought article, Roy neglected to include the effects
of wave-cancellation/interference at the source resistor in his
example. I don't think that Walter Maxwell has expressed an opinion on
this particular subject of dissipation in the source resistor of a
voltage source as specified by w7el. In a real-world amplifier, Walt
asserts that the source resistance is non-dissipative while, for his
food-for-thought examples, Roy specified a dissipative source
resistance designed to eliminate reflections. Again, what he forgot to
include is redistribution of energy due to wave cancellation, a
concept well understood in the field of EM wave optical physics. He
apparently does not understand the mechanism whereby the conservation
of energy principle is honored so he is forced to falsely assume that
reflected energy is not incident upon the source resistor. Nothing
could be farther from the facts of physics as understood for decades
in the field of optical physics. I was taught constructive/destructive
interference energy concepts in my vector analysis classes at Texas
A&M University during the 50's.

The only time photons are not generated is during DC steady-state with
no AC signal applied. If you can see the electron beam inside a vacuum
tube (and I have), the electron beam is necessarily emitting photons.
If the field surrounding an electrical current is detectable, the
electrons are emitting photons.

Yes.

This post is sufficiently informing for many. Others may take its lead and derive EXACTLY how much resistance, heat, power from the data provided by Walt and confirm the bench experience of real resistance within the source.

This response quoted above also corrects my mis-observation of my having the only perception of this universally experienced phenomenon. By count, we are up to two who acknowledge what is obvious.

A lot of folks, make the same mistake, in thinking that Electrical
Ground and RF Ground are the same thing. They, clearly, are NOT, the
same thing or even close to the same thing, unless you happen to be
living on a Salt Marsh. Ground Rods, of any kind, are only Electrical
Grounds. Rf Grounding is a Totally Different bag of cats. RF Grounds
need to be engineered, by someone who is familiar with Antenna Design
and Installation Procedures, for the particular Antenna and landscape,
where the antenna is to be installed.

trying to discuss modern methods.

They should know that the physics and the math go together.

Maxwell did the aether model and the math for it.
In the model were the rotational oscillations of massive, compressible
magnetic substance.
The electricity was masless and incompressible.

Now we know that no magnetics substance and that the electricity (electrons)
has mass and that the electron gas is compressible. It means that light is
exactly like sound.

The above was obvious for Royal Society. But the math for the oscillating
whirls was the new.
In result in the science history is wrote "that Maxwell's model was stripped
away and just the equations remain".

The math for whirls was done by Helmholtz but without the oscillations. The
math for the oscillating whirls (EM) must be in schools. In schools are all

theories.

Modern metods are in the plasma physics.

no they aren't... look above, which text did you write and which did i
write?

i used to use outlook express like you are using, and it is bad. get
something better if you like to quote lots of text.

> In schools are all theories.

the only purpose for disproved theories in schools is for historical
context. sometimes it is useful to show students what doesn't work so
they don't waste time repeating past mistakes. aether theories are
one that is taught and then demonstrated in class as incorrect. once
the student makes the measurements they get a better feeling why
aethers are bogus.

Hi all

>Walt is not espousing a theory
Please, give me a name to name it.

> They have what is called "internal consistency."
Who are "they", Walter's propositions?

Before advance more Richard. All off you share or ascribe a
"existence" notion determinated by observator measurements? It is long
time philosophical question remember, trees, sounds...

> A confused statement
I know. Communicate minds takes its time. It is more easy as we share
the basic assumptions neccesary for that. It's what I'm trying.

> Two light waves can pass through each other at the same point in space without affecting
or interacting with each other because they are *not collinear*.

Why? As I learnt superposition principle not depends of collinearity.
English Oxford dictionary I have, define "Interact" as "act on each
other", similar concept in spanish I think. I learnt superposition as
involving 'no interaction'. both waves still identical to itself in
superposition (in nonlineal systems they certainly can interact).

> For pure sinusoidal waves, the transmitted wave, the re-reflected wave, and the
constructive interference wave are all coherent and collinear and merge into a single
forward wave flowing toward the load. The component waves become inseparable.

I can agree with above paragraph but, for that I just said, I think
not with this...

> Therefore, any two coherent RF waves traveling in the same direction in an RF
transmission line, will interact and have a permanent effect.

As I undestand, two o more superposed waves can be added or
substracted to render a resultant but we do not call that interaction
(I am excude here the observer -Richard's observations- notion for not
to get out of point).
Two traveling waves with same direction, frequency and phase would be
certainly indistinguishable of a single one equal to the vectorial sum
of the two cited, by our instruments. For my conceptual notions adding
or substraction are not interaction. I am not dare to advance more on
your kindly answers because this notions are hardly vinculated to our
issue. Would be appropiate "slow down" a little and work on it?, what
do you think?
.....

About Roy's differences, At two opportunities I read here issues
(problems?) about Rs. Why do not you agree in a simple initial
Thevenin model? (it is a question not a suggestion, I don't know how
correctly translate my sentence).

Cecil, can you find a "energy distribution" concept compatible with
special case of unidirectional line space where all of you can agree?
Transmission/reflection notions (about energy) do not represent that
concept?
A mental exercise (it is doesn't a criticism, only a idea, remember I
am interesed in your analogies): Suppose we are not capable to
perceive any light (or realize of it), only HF spectrum; could you
share (agree?) concepts with our other "blinded" colleagues :>) to
analize this stuff?. I believe that is absolutly a "Yes" (of course
you could use your knowledge in optics to devise good RF arguments,
but you have to silence it, because you know they "antenna senses" are
note light sensitive.
....
> Eugene Hecht, in "Optics", describes standing waves of visible light in free space. I'm not sure that humans can "see" the standing wave detail because the frequency is so high, but standing waves of visible light can certainly exist in free space.

In perfect vacuum free space without any material stuff to reflect
light or bring our retinas into the region in some way?

Hi Miguel,

Walt is presenting data to support a hypothesis (explanation for the
occurrence of some specified group of phenomena).

>> They have what is called "internal consistency."
>Who are "they", Walter's proposittions?

Models have what is called "internal consistency."

>Before advance more Richard. All off you share or ascribe a
>"existence" notion determinated by observator measurements? It is long
>time philosophical question remember, trees, sounds...

You are getting into intederminancy. Is this more about Truth again?
Truth is funny and sad, but not very useful.

>> A confused statement
>I know. Communicate minds takes its time. It is more easy as we share
>the basic assumptions neccesary for that. It's what I'm trying.
>-------------
>> Two light waves can pass through each other at the same point in space without affecting
or interacting with each other because they are *not collinear*.

You don't need "because" or anything that comes after it. It sounds
like superstition.

>Why? As I learnt superposition principle not depends of collinearity.
>English Oxford dictionary I have, define "Interact" as "act on each
>other", similar concept in spanish I think. I learnt superposition as
>involving 'no interaction'. both waves still identical to itself in
>superposition (in nonlineal systems they certainly can interact).

Yes.

>> For pure sinusoidal waves, the transmitted wave, the re-reflected wave, and the
constructive interference wave are all coherent and collinear and merge into a single
forward wave flowing toward the load. The component waves become inseparable.

More superstition. There is nothing about sinusoidal waves that make
them coherent or colinear. This is probable a problem of poor English
from a native speaker - very common.

>I can agree with above paragraph but, for that I just said, I think
>not with this...
>
>> Therefore, any two coherent RF waves traveling in the same direction in an RF
transmission line, will interact and have a permanent effect.

Permanent - another superstition (until the end of time + 1 day?).

>As I undestand, two o more superposed waves can be added or
>substracted to render a resultant but we do not call that interaction
>(I am excude here the observer -Richard's observations- notion for not
>to get out of point).
>Two traveling waves with same direction, frequency and phase would be
>certainly indistinguishable of a single one equal to the vectorial sum
>of the two cited, by our instruments. For my conceptual notions adding
>or substraction are not interaction.

They interact on the load, not on each other. But as you now phrase
it, being colinear as an initial condition rather than as a subsequent
result, then the possibility of both sources (acting as opposing
loads) cancelling each other may follow.

This says nothing of waves interacting, however. That is sheer
nonsense.

Let's put it another way and agree entirely! Accept that two coherent
waves that are colinear do interact - but only if colinear. That must
be some very, very special mathematics that allows no error in
colinearity (perfection is demanded). Perfection does not exist, the
necessary colinearity does not exist, interaction does not exist.

OK, so near perfection is suitable. -sigh- How much is "near
perfection?" Within one millirad? What is it about 1.000001 millirad
that extinguishes interaction? Oh, 1.000001 millirad works too, but
not more. OK, what is it about 1.000002 millirad that extinguishes
interaction? Oh, 1.000002 works too, but.... Pretty sloppy argument,
I don't see a formula for when interaction stops working, this means
that all angles cause interaction, but we do not see interaction at
any angles.

This "take it on faith" kind of creation (create it as you go) science
returns us to vaudeville (Miguel, maybe I should use the term Commedia
dell'Arte to explain our vaudeville).

"God said let there be a photon... go forth and multiply"
[- low budget creation science definition
for the Sun(s) taken from the first printing of
"How to Kick Start Genesis on One Quanta a Day."]

(Adam, muttering) what a day.... what a day.... (suddenly inspired)
What a beautiful photon-set we are having this, this, this. I think I
shall name this "evening" Eve! What a beautiful photon-se.... Damn!
(whoops - oh I beseech thee to forgive my utterance) it got dark
quick. How long before photon-rise? Are we on photon savings time?

>Suppose we are not capable to

Richard-

I have a steel well pipe that is approximately a quarter wave on 40 Meters. Even though it is buried, why wouldn't this work as the bottom half of a vertical dipole?

I tried it with a mobile whip as the vertical element. It worked better than I expected, but not really well.

Hi Fred,

One perspective of the radial field is that it shields the radiator
from the loss of ground. However, that simplification disguises the
fact that the radials radiate too - and unproductively. When every
radial's radiation is taken into consideration, opposite radials (each
one that is 180 degrees from the other) cancel.

That aside, their benefit is they conduct better than dirt. What this
means is more power goes into copper/steel instead.

Now, if we consider your well pipe, it goes deeper into that lossy
dirt and the deeper it goes, the more dirt the return signal (to the
other, the vertical radiator) has to go through. More loss than use.

OK, another reason. For as poor/well as dirt may conduct, it too has
skin effect. This means at some distance into the dirt, conductivity
plummets because of skin effect. Deeper yet, and the skin effect loss
increases at a quick clip.

As skin effect is frequency dependent, at really low frequencies, your
well pipe has some advantage. This frequency range is suitable for
working lightning whose top end is 1MHz. At 7 MHz, there's no point.

>I tried it with a mobile whip as the vertical element. It worked better
>than I expected, but not really well.

Which shows you how crummy the whip is because what well pipe there
was that was above ground was doing the job of the whip.

Step back and look at the big picture using your analogy of a vertical
dipole with half of it buried. Now, convert that buried half into
multistrand. Bend each strand 90 degrees so that each strand just
rides an inch or two above ground with all of the newly bent strands
in a flat circular spray around the upper half. Walla! as the French
say.

>I hard trying don't run out so much off topic :>)

I am not out of topics. It is to your:
"To concentrate light we only need a piece of glass, to do the same on
HF RF region we need large wire antenna arrays. Because of this we
often need (or employ) very differents models to deal with the "same
thing". Probably Maxwell equations solve all of them, but they are
difficult ladies to deal :>)."

You should read the Maxwell:
http://en.wikisource.org/wiki/On_Physical_Lines_of_Force
Maxwell described the model in English and in the math. English is not
difficult ladies to deal for you.

After this you understand why: "that Maxwell's model was stripped away and
just the equations remain".
Light and radio waves are exactly like sound.

Source record: 9540

how about this, i'll really mess things up. all comments assume
linear media or circuit elements and sinusoidal stead state conditions
(all transients ignored).

Standing Waves are a figment of your instrumentation... it is a well
known method to choose either voltage or current to do calculations in
a circuit, knowing that the other can always be calculated given the
impedance. this works for distributed as well as lumped circuits. it
is a consequence of superposition and ohms law in the generalized
complex form. This is a trap when looking at traveling and 'standing'
waves when there are reflections. Since you are only seeing one of
the components of the wave you get the impression that the standing
wave is indeed concentrating the energy and all the resultant effects
at 180 degree intervals. you must however look at both components to
get a full picture.

Wherever there are standing voltage wave peaks there are also standing
current waves 90 degrees (in distance) along the line from them. And
while you can calculate the power of the voltage wave peaks as V^2/Z,
you can also calculate the energy of the current wave peaks as I^2*Z.
Of course you can really get yourself confused if you consider the
lossless transmission line with a perfect short or open end... in that
case at those peak voltage and current points the Z is infinite or
zero respectively which gives you zero power in either case. Now to
REALLY have fun, integrate the power at those points into the energy,
of course the integral of zero is always zero.

Want to get even more confused. Look at an animation of the standing
waves (EITHER current OR voltage) over one full cycle in time, there
is a peak where the standing waves along the line all reach a peak
value at once, then 90 degrees later the whole line is zero, then
another 90 degrees and there is an opposite peak. Think carefully
about the zero point, where did the energy go? Surely it doesn't mean
that all the energy stored in those waves has left the line? that
would require some external storage and faster than light energy
transfer, a mean trick if you can do it!

Ah, but wait, the current wave is 90 degrees out of phase with the
voltage, so the energy has a place to go, into the other component!
but remember, when that component peaks the impedance is wrong so
there is still no energy. But of course then everything does balance
out, no energy in one standing wave transfers perfectly to the other
standing wave 90 degrees later in time and space.

conclusion: Standing waves are a figment of your instrumentation, be
that eyes seeing the peaks and valleys of a physical manifestation of

them, a fluorescent lamp showing them as you run it along an open wire line, or a voltmeter measuring them... they don't exist except when they are observed, therefore they have no physical existence... much like whats his name's cat.

On May 30, 9:04 pm, Richard Clark <kb7...@comcast.net> wrote:
> There is nothing about sinusoidal waves that make
> them coherent or colinear.

Please Google the two words: I probably should have use "collimated"
instead of "collinear".

"Electromagnetic radiation is coherent when the photons are produced
in such a way that they are in phase with one another and incoherent
when the phases of the photons are random."

"Collimated light is light whose rays are nearly parallel, and
therefore will spread slowly as it propagates. The word is related to
"colinear" and implies light that does not disperse with distance
(ideally), or that will disperse minimally (in reality)." Note that a
coaxial transmission line results in minimal dispersion for an RF
wave.

Coherent photons are identical except for direction. Collimation makes
their direction close to identical.

> Permanent - another superstition (until the end of time + 1 day?).

Wrong definition of "permanent". Not permanent in time - permanent in
the sense that the process is irreversible in time.

> >As I undestand, two o more superposed waves can be added or
> >substracted to render a resultant but we do not call that interaction

We do call it interaction when the two waves are coherent and
collimated. Again, here is what Florida State University has to say:

"... when two waves of equal amplitude and wavelength that are 180-
degrees ... out of phase with each other meet, they are not actually
annihilated, ... All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ... Instead, upon meeting, the photons
are redistributed to regions that permit constructive interference, so
the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction
of light."

They are talking about wave cancellation such that happens at the
surface of the thin-film on non-reflective glass. The result of wave
cancellation is permanent and the energy that would have been
reflected is reversed in direction actually making the underlying
picture brighter. That sounds permanent to me.

> They interact on the load, not on each other.

If that were a fact, you could separate them on their way to the load
but such is impossible. It doesn't matter where they came from, two
coherent, collimated waves interact when they are superposed and
become inseparable from that point on. Only incoherent or uncollimated
photonic waves can be separated.

And if you allow interaction at the load, why not allow interaction at
an impedance discontinuity which is much like a load and is indeed
where the interaction happens.

> This says nothing of waves interacting, however. That is sheer
> nonsense.

Wave cancellation is an obvious proof of interaction. Let's see you
recover two waves that have been canceled.

> Let's put it another way and agree entirely! Accept that two coherent
> waves that are colinear do interact - but only if colinear. That must
> be some very, very special mathematics that allows no error in
> colinearity (perfection is demanded). Perfection does not exist, the
> necessary colinearity does not exist, interaction does not exist.

"Perfection does not exist" is the self-fullfilling last gasp non-
perfect argument of the ignorant. Close enough to collimation
perfection does exist in an RF transmission line or in an
interferometer. The coherent photons in an ideal coaxial transmission
line are forced into a state of collimation. Is it perfect single-file
collimation? Of course not, but it doesn't have to be perfect.
Confining the photons to a certain cross-sectional area is all that is
required in the real world. Do all the photons have to be perfectly
coherent? No, just the majority of photons from the transmitter.

Does a 1/4WL non-reflective coating on glass perfectly cancel 100$ of
the single-frequency coherent incident laser light? Not in the real
world, but you can use your own eyes to detect that it is doing a
pretty good job. The Melles-Groit web page says:

"In the absence of absorption or scatter, the principle of
conservation of energy indicates all 'lost' reflected intensity will
appear as enhanced intensity in the (forward) transmitted beam. The
sum of the reflected and transmitted beam intensities is always equal
to the incident intensity. This important fact has been confirmed
experimentally."

Those above alluded-to experiments seem to contradict what you are
asserting. Do your own experiments disprove what that web page is
saying? If so, where did they go wrong?

Miguel, please see my above posting in reply to Richard's posting.

> As I learned, the superposition principle does not depend on collinearity.

Please change "collinear" to "collimated". The results of
superposition can be reversible or irreversible. If the photons are
not coherent and/or not collimated, the results of superposition are
reversible in the sense that each separate wave can be recovered. The
results of superposition of coherent and collimated waves (traveling
in the same direction) are not reversible, i.e. the ability to recover
the separate waves has been lost forever. Two coherent/collimated
waves that are superposed indeed do interact. Non-reflective glass is
a typical example. The external reflection interacts with the internal
reflection causing the reflections to undergo wave cancellation and
the total energy in the two superposed (canceled) waves to change
direction and make the picture brighter. The Melles-Groit web page
says:

"This important fact has been confirmed experimentally."

> As I understand, two or more superposed waves can be added or
> subtracted to render a resultant but we do not call that interaction.

I call it interaction when the identity of both waves is lost which is
what happens during wave cancellation. It is not interaction when the
identity of both waves is not lost. The results of superposition can
have either outcome.

> For my conceptual notions adding or subtraction are not interaction.

If you add a pint of water to a pint of water, the two pints of
identical molecules interact, analogous to one joule of coherent/
collimated photons added to another joule of the *identical* photons.
The results is two joules of identical photons, indistinguishable from
each other. If the superposition process is reversible, interaction
has not taken place. If the superposition process is irreversible,
interaction has taken place. Both outcomes are possible depending upon
the initial conditions.

> Why do not you agree in a simple initial Thevenin model?

It was Roy's idea to avoid the abstract Thevenin model and go with a
similar real-world source, probably because of the admonition in
"Fields and Waves ...": "... significance cannot be automatically
attached to a calculation of power loss in the internal impedance of

the equivalent circuit."

> Transmission/reflection notions (about energy) do not represent that
> concept?

The mistake that virtually all RF gurus are making, including w7el in his food-for-thought article, is assuming that reflection is the only mechanism capable of redistributing reflected energy back toward the load. But it has been known for decades in the field of optical physics that EM wave cancellation can also redistribute reflected energy back toward the load. It is well known that the reflected energy lost through the use of non-reflective glass causes the picture (load) to be brighter. If w7el would simply take the time to calculate the wave cancellation energy (constructive or destructive interference) at the source resistor, he would understand exactly where the reflected energy goes. The conservation of energy principle allows nothing magic (like reflected waves containing no energy or EM waves that do not move at the speed of light).

> Suppose we are not capable to
> perceive any light (or realize of it), only HF spectrum; could you
> share (agree?) concepts with our other "blinded" colleagues :>) to
> analize this stuff?

It is very useful to say: If our eyes could see the RF waves, what would we see? We would see the same thing we see with visible light waves, just at a different frequency (wavelength).

> In perfect vacuum free space without any material stuff to reflect
> light or bring our retinas into the region in some way?

Of course, we would need some sort of irradiance detector more sensitive than human retinas. Partially mirrored glass is often used to route a sample to a detector. If we detect standing waves in a 10% sample, we are pretty sure that standing waves exist in the rest of the sample.

ah, but in this case consider that you have a pint of blue water moving to the right and a pint of red water moving to the left to be a better analogy to currents of the waves moving forward and backward in the coax. there are then 3 possibilities:

1. the two mix and cancel giving you 2 pints of purple water not going anywhere.
2. the two bounce off of each other now giving you red water moving right and blue water moving left.
3. the two pass by each other not mixing at all and continue on their way.

if 1 happened you would indeed cancel the waves and end up with a spare pile of electrons not going anywhere. while this may be adequate for a mechanical analogy it doesn't say where the energy of those two moving pints went so is obviously wrong.

number 2 conserves energy at least.

number 3 also conserves energy and gives the same energy distribution as 2.

since electrons aren't colored it makes number 2 and 3 indistinguishable, so clearly the result is that both waves continue on their way undisturbed by the other... which is what is observed in all cases of em wave interaction in linear media.

no need, just look at the lines on a hologram, that is the map of the
interference patterns from the reflected and reference laser beams.

No, no, no. I am NOT talking about forward and reflected waves moving in opposite directions. I am talking about two coherent, collimated waves *MOVING IN THE SAME DIRECTION* in an RF transmission line away from an impedance discontinuity - either two waves moving forward toward the load or two waves moving backwards in the opposite direction toward the source. Such multiple wavefronts occur at impedance discontinuities because of multiple reflections.

Forward and reflected waves (waves moving in opposite directions in a constant Z0 environment) do NOT interact. At an impedance discontinuity, the component reflections and transmissive waves do interact if they are coherent, collimated, and MOVING IN THE SAME DIRECTION.

Oh yeah, duh ... brain fart - if one slants the partial mirror
detector, one can spread the interference patterns out to an optimum
pattern for viewing by a human eye.

Miguel, I want you to note how David clearly exposes the failure of a
metaphor, using the metaphor's own analogy.

This is the danger of trying to explain one system in terms of another
without knowing how either work.

It also reveals in shades of deep purple, how the visual system lies
to us, and we believe we see the Truth.

So, for metaphors and analogies, when the reader knows better, its a
lark (an amusing adventure or escapade); or when the writer knows
better, its a lark (behavior in a mischievous way).

If you both don't know better, its a lark (activity regarded as
foolish or a waste of time by the rest of us).

Carefully parse the following:
"Truth is a lark."

Actually Miguel, I want you to note how a simple semantic misunderstanding can lead to false assumptions that propagate to: 1. false assertions, 2. accusations, and 3. character assignation. I said earlier that I was referring only to coherent/collimated waves that are TRAVELING IN THE SAME DIRECTION. K1TTT apparently missed that caveat and was simply confused about what I had said. Based on that false assumption, Richard, as usual, jumped on the "kill the messenger" bandwagon. He doesn't seem to realize that he has to prove quantum electrodynamics to be wrong to prove me wrong, a feat that no mortal has yet accomplished.

add another condition and i might buy it... their polarization must be
the same... if you satisfy ALL those conditions then i believe you
would not be able to separate the waves and you could combine their
amplitudes. but that still doesn't mean they are interacting, just
that their fields always happen to be aligned... now if you are an
engineer like i am and deal with macroscopic processes i would
consider it perfectly logical to add the fields in a linear medium and
carry on with a single wave in each direction created by an infinite
series of reflections... HOWEVER, if i switch my hat to the scientist
part of my job title and i was working in photons I would come to a
point where it would be impossible to divide the last photon and
things would fall apart.... fortunately the ham/engineer side usually
outvotes the scientist part and i take the infinite summation and call
it a day.

If they are coherent, their polarization must necessarily be the same
at the same point at the same time. I specified that they are
coherent, collimated, and traveling in the same direction. I'm not
omniscient so if that's not enough boundary conditions, please
enlighten me.

Walt, W2DU wrote:
"Rp is a non-dissipative resistance, not a tesisTOR with physical characteristics."

To nit pick a little, I think some dissipative resistance is found in the output impedance of a Class C amplifier when you average over an RF cycle.

Although rp (dynamic plate resistance) is defined as the change in plate voltage divided by the change in plate current when an increment of plate voltage produces an incremantal change in plate current, plate resistance goes down as plate current goes up.

Rp can be very low but not zero when a tube biased beyond its cut-off is pulsed on heavily duting the RF cycle. In saturated conduction the voltage drop actoss the tube can be very low and any change in plate voltage would result in insignificant change in plate current.

When a Class C amplifier is switched into heavy conduction by its grid, its DC resistance is low and its power suppy may be low in resistance too. During the conduction part of the RF cycle, the impedance looking back into the amplifier`s putput is low also. During the switched-off part of the amplifier`s cycle, the impedance looks like an open circuit. Over an entire cycle, the tube`s output impedance has an average value.

A pi-network is an impedance transformation device which does not completely isolate its input from its output, so a tube on its input has its shunt impedance transformed to some value across its output. Its resonance can linearize the signal.

Best regards, Richard Harrison, KB6WZI

It doesn't matter. At HF wavelengths, the last photon is not going to have an appreciable effect (but maybe at gamma-ray wavelengths). The collapse of the probability function indicates that if one runs a large number of trials, n% of those very last photons will be reflected and (100-n%) of them will be absorbed. That probability function has never been proven to be wrong.

I have no idea why an otherwise knowledgeable individual could be argumentative concerning this subject.

Hi Richard,

On reviewing the paper you sent me I've given a lot of thought concerning the source of the induced current flowing in the external resistance, R, the load of the plate of the tube. You say the source of the I^2R power dissipated in R is plate resistance, Rp. However, as I read Par 7.2 on Pages 140 and 141, the reality of Rp is described in there, but only indirectly, thus requiring a deep inquiring mind to ferret it out. For me, it takes a leap and a stretch to understand that Rp is the source of the I^2R power delivered to R.

In Par 7.2 the author says this power is supplied by the kinetic energy of the electrons in the beam. It takes no great amount of mental concentration to understand that that statement is true. But

where I see a tangential approach to describing Rp is in the statement that “Since each electron in the beam faces a decelerating electric field due to I^2R, it loses an amount of energy eIR during its flight from the grid to electrode P.” This energy is lost, of course, because the plate voltage is decreasing due to the increase in voltage drop IR across R, caused by resistance Rp. We know, of course, that although Rp is real, it is non-dissipative because it is not a physical resistor, but is only the result of the ratio deltaE/deltaI.

Again quoting from Par 7.2, “It is evident that IR must be smaller than the voltage to which the electrons have been accelerated in order that they reach P.” I understand this to be caused by Rp. However, this still doesn’t make clear that Rp is the source of the I^2R power. Only until we see the quote “…the total power lost by the electrons in the interelectrode region is (equation 7.12), which is equal to the heat power dissipated in the resistance (R) by the induced current.” does the reduced power seem to have any relevance to Rp.

Now continuing the quote from Par 7.2, “The remaining part of the electron’s kinetic energy is transformed into heat energy when they strike electrode P.” It’s my understanding that this is the energy that’s dissipated in the plate, causing it to heat.

However, the relationship between energy lost in the interelectrode region and the energy dissipated in R seems to say that Rp is the source of the energy dissipated in R, but it is difficult for me to accept that relationship. I find it difficult to accept that a loss in energy due to decelerating field in the interelectrode region could be the source of the energy dissipated in R.

Richard, can you help me out here in understanding this concept, if it’s really true? It seems to me that the loss of energy due to Rp is simply energy that was never developed in the first place due to the deceleration of the electric field in the interelectrode region.

Walt

Within close proximity (about 3 to 5 times the wire separation), you
still have a sense of each wire. Further away, there is so little
difference in distance to either of them, that they both add with
cancellation.

>I vaguely remember we used to use twin lamps, wired backwards for this

This must be the cobwebs you speak of. Other than LEDs (and I think
you would have specifically said so if your indicators were these),
lamps have no sense of current direction. Example, what would happen
if you reversed the plug to your table lamp? Would it suck light?
Have you ever put in a fluorescent bulb with the wrong polarity?

the solar wind is well know and easily studies with the satellite data
available today. but it is not an aether, the interplanetary plasma
does not propagate the light from the sun, it just gets in the way.

I have vague recollections of a reflectometer using diodes, lamps and
300ohm twin feeder. Maybe in an old copy of Radcom...

1966. twinlead tuning indicators

Newsgroup: rec.radio.amateur.antenna
Date: 2010-05-31 22:20:03 UTC
From: rb <rbig@cox.net>
Message-ID: <7SUMn.40647$wV2.6070@newsfe23.iad>
Source record: 9461

Memory has usual cob webs. Help clear it.......

When I feed twinlead, seems I might use a small fluorescent bulb to show how it's doing. If a small fluorescent bulb will do this, do I just tune for "max smoke" while holding it near the twinlead? Can't recall if a small flourescent bulb will do this or not.

If radiation is cancelled, not sure how it would fire.

I vaguely remember we used to use twin lamps, wired backwards for this purpose. One way you had SWR on one side; the other way you had SWR on the other side. Neither light being lit meant good SWR.

RB-

My cobwebs are probably worse than yours. As a teenager back in the 50s, I used a "Full Windom" antenna (off-center-fed-dipole) fed with 300 Ohm TV twin lead.

The SWR measurement circuit I used probably came from an ARRL publication. It consisted of two 6 Volt dial lamps connected to each end of a section of twin lead. I think it was two or three feet long. The whole thing was taped to the transmission line. There was a connection at the center of this on one side to one side of the transmission line.

As I understood it, one lamp was supposed to glow and not the other. I think both of mine glowed, but one was definitely brighter. Of coarse I did not know what I was doing and had no real understanding of SWR. I made contacts, so never worried about it!

Using a fluorescent tube, I would expect it might glow at points along the transmission line where voltage was high and extinguish where voltage was low. With a low SWR, there would be no high voltage points. Or maybe no nulls?

I can only relate an experience I had in my house in Minnesota. We had a
long hallway and I could just shuffle my feet and the fluorescent light
I was carrying lit up from the accumulation of charge. Free, well almost
free light. A guy in the S.F. bay area has a house near a radio
transmitter and his garage is pretty well lit by 4 foot tubes he has put
around.
YMMV.

Try this.. I had an Ampex tube amplifier driving a high voltage
transformer and as the music danced (in my head) the patterns were
dancing to the same beat. I just drove the input of the Ampex with the
output audio line. Yes, that was in the 70's and yes we were all stoned.
I don't think that anyone else tried that combination, but it was way cool.

Whatever it was it was sure pretty and tube had ripples from both ends
that we could just watch. You would almost have to see it to believe it.
Kind of like visible standing waves going the length of the tube.
I think that kind of thing would kill any new solid state amps.

The LEDs that suck light are normally referred to as DEDs (Dark Emitting
Diodes)

Hi Bill,

I just now ran into one of your earlier posts regarding insomnia. I
have some important info for you, which I'll email to you if you'll
give me your email address in a email to me, which is walt@w2du.com.

Walt

Hi all

First the first: Sorry Szczepan, do not feel upset I wanted to say
"Me" don't go off topic with my own answers, not you.

Very interesting comments!
I think we must agree on meaning of words and basement concepts
employed to discuss these matters, otherwise we end up talking about
different "things" (Babel curse what confuses our tongues). If we do
not agree with meaning of, for example, "interaction", how can we
reach an agreement on much more complex things that depend on this
word/concept?
This is not a criticism to anyone, is only my point of view about what

I think is a partial source of apparently irreductible positions in the group.
I believe Richard, K1TTT and me, have sinchronized minds about "Interaction" word/concept meaning. I suppose must be a more deep underlying assumptios that make it possible. However I believe I understand the "idea" underlying Cecil concept about "interaction" and I believe I can "see" his point, To me, Cecil's interaction concept it is a very common idea, I do not think Cecil be a "hard to die" man :>)
I think we have to do our more honest efforts to sinchronize ideas.
I do not want to go off topic, but let me bring a couple of thinkings to the table (they are not mine).

* Students come into our classrooms with an established world-view, formed by years of prior experience and learning.
* Even as it evolves, a student's world-view filters all experiences and affects their interpretation of observations.
* Students are emotionally attached to their world-views and will not give up their world-views easily.
* Challenging, revising, and restructuring one's world-view requires much effort.
(from http://srri.umass.edu/topics/constructivism)

Why these above things would not happen to me?
.....
Returning: Cecil, given A+B=C, do you you see C as result of an interaction (or mutual action) among A and B, or C a simply result of A added to B?
Another question to clarify my undestanding of your propositions: do you see waves interacting themselves in a discontinuity, or you see them interacting with the discontinuity? or both phenomena at the same time?. Change discontinuity for load and please tell me.

Richard, you said: -"Because" leads to superstition-; you are pointing to causal relations?
I believe was you who said dislike representations, if it is yes, were you aiming to create mental images of physical phenomena?
Here we often use the word "methafor" in figured sense instead "analogy", for example, "my car it is as strong as a locomotive" it is a true methaphor. In metaphor, there are two levels or terms: the real (my car) and evoked or imaginary (locomotive). Coulored water is it a true methaphor or an analogy?

Simple analogies as useful things until one (or more) of they not work... then, ciao analogy..!, not so bad :>), however... notice!, our ideas are not equal to the "out there" world. Concepts, models, (mathematical models also, of course)... are not they our mind's "analogies" "out there" sensorial/injstrumental perceived world?
These are not trivial epistemology issues, our "observer" leads directly to the question about "Is the moon there when nobody looks?" (N. D.Mermin). When we go out of our classic-simplistic-realistic-traditional ham world... "we are in troubles, Houston",

slippery soil!, I make the sign of the cross! :>)

K1TTT said: -Standing waves are a figment of your instrumentation-. My dictionary translates "figment" as "product" or "chimera", please, tell me what word should I use to correctly read the sentence?

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

"analogy", for example, "my car it is as strong as a locomotive" it is
a true methaphor. In metaphor, there are two levels or terms: the real
(my car) and evoked or imaginary (locomotive). Coulored water is it a
true methaphor or an analogy?

>Simple analogies as useful things until one (or more) of they not
work... then, ciao analogy..!,

Radio waves and sound are in full analogy.

>K1TTT said: -Standing waves are a figment of your instrumentation-. My
dictionary translates "figment" as "product" or "chimera", please,
tell me what word should I use to correctly read the sentence?

Waves always travel (pressure or voltage pulses). If the wave interact with
the reflected one than the places where the pressures/voltages change are
standing.

The reflected wave cam be weaker if the mirror is partialy transparent (or
if an absorbtion take place).

The aether in sense of medium for light propagation.

> the interplanetary plasma
does not propagate the light from the sun,

In the interstellar medium (ISM) are ions, electrons and dust.
http://www.astronomynotes.com/ismnotes/s2.htm

The medium are the electrons ony. The rest are contaminations, like the fog
and dust in the air for the sound waves.
Do you see any sensible another solution?

in this context figment=product. often used to describe something
that is a result of an over active imagination. the only reason you
can see standing waves is because a measurement or observation makes
them look like they are 'standing' when it is really the interaction
of two or more regular traveling waves.

the electrons can not do it either. there are not enough of them and
they move too slowly in the plasma to propagate light. these are
easily measured, you can watch the density directly using the ace
satellite web page and calculate the speed of longitudinal waves if
you want, but it won't be anywhere near light speed.

Of course, there are all types of "addition", e.g. arithmetic,
algebraic, voltage phasor, Poynting vector, scalar power,
superposition, merging, mixing, ... Which type of "addition" is
appropriate depends upon the nature of what is being added.

Simply put, if A + B = C creates an irreversible result, then A has
(obviously?) interacted with B. If the result is reversible, then A
has not interacted with B. For the great majority of cases,
superposition does not result in interaction. For the great majority
of cases, interference does not result in interaction. For some
(special?) cases, superposition (plus associated interference and wave
cancellation) results in interaction and the result is irreversible.
Non reflective glass is an example of wave interaction. The internal
reflection cancels the external reflection and the energy in those two
reflections changes directions. A Z0-match at an impedance
discontinuity in an RF transmission line is another example. Again, if
two waves are coherent, collimated, and traveling in the same
direction, those two waves will interact, i.e. their superposition
result is not reversible.

what exactly is the 'interaction' and why is it unique to that
special coherent, collimated, etc, case? if two waves can 'interact'
in that case there should be other evidence that they can interact in
other situations. just because a+b=c doesn't mean that a and b have
magically disappeared for some reason, in mathematics c=a+b is just as
valid and implies that c is made up of a and b... or using your water
analogy, adding one pint to another pint doesn't magically cause them
to 'interact' in some way, the original water is still there, perhaps
indistinguishable from each other, but still there. it may be
convenient to represent the result of summing an infinite series of
reflections as a single number, but it is not necessary.

Is it not obvious that when two reflected waves cancel in one direction, as at the surface of a 1/4WL thin-film coating on glass, and their combined EM energy is redistributed in the opposite direction, that those two waves have interacted, i.e. have suffered a permanent change and have lost their original identities?

Is it not obvious that when two waves are traveling two different paths where the incident angle is, e.g. two degrees, that those two waves will superpose and interfere throughout a certain space after which they emerge intact, unaffected, and have obviously not interacted, i.e. they suffered no permanent change and have maintained their original identities?

Did superposition occur in both cases? Yes. Did interference occur in both cases? Yes. Did wave cancellation occur in both cases? No, just in the non-reflective glass case.

Consider a transmission line with an SWR of 5.83:1. The sourced power is 100 watts. The forward power is 200 watts. The reflected power is 100 watts. All of the reflected power is redistributed back toward the load at a Z0-match through reflection and wave cancellation. Zero reflected power is incident upon the source.

Does the 100w source wave lose its identity when it merges with the 100w of redistributed reflected wave to become the 200w forward wave? Is the steady-state load energy coming from the source wave or the redistributed reflected wave or both? Seems to me, it is obvious that the two original component waves have interacted and lost their original identities for good if they are pure coherent sine waves traveling in the same direction confined to a coaxial transmission line.

1992. What to use for an underground transponder?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-06-01 15:21:00 UTC
From: Clint Alexander <clint@cdalexander.net>
Message-ID: <paOdnc5uFrnIuJjRnZ2dnUVZ_oCdnZ2d@ptd.net>
Source record: 9492

I want to make a simple transmitter to use as a locator beacon. But the source would be in the ground (anywhere between 3 - 10ft). The receiver would need to locate it, much like a metal detector would except it would be a small hand-held "wand" with a LCD giving the direction and signal strength.

I'm not sure of the signaling to use therefore I'm not sure of the antenna required. But, it would need it to follow part 15 of the FCC rules/regulations (none hazardous and allows required interference).

I am completely new at this sort of technology. I have created circuits before using L555 timer, 4046Phase Loop, etc. But I've never went farther than building simple demonstration circuits. I wondered if there was anyone on this list that may be able to shed some light on what I would need and/or how I would use them (a schematical description), or even point me to the "yellow brick road".

Thanks!

Try burying a WiFi dongle and see what you get. 2.4gHz has the advantages
of being COTS (commercial off the shelf technology), easy to build
directional antennas, cheap and easily adapated to digital technology.

It also has the advantage of being legal in almost (if not) every country
in the world.

I'm not sure it will reach through 3-10 feet of dirt, but I expect that
anything much above 15khz will have that problem.

Geoff.

>there, but only indirectly,

Hi Walt,

The point I have been emphasizing is that the plate resistance is
real, where real is the conventional meaning of heat following
current. The authors expresses this in all the conventional usages
and mathematical expressions of heat, velocity, kinetics, mass,
collision, current, voltage - everything you would find in an ordinary
resistor.

As for indirectness, no single section encapsulates the entire topic.

However, the remainder of the chapter does. Don't stop early to
examine the sidewalk to ignore the destination.

As so often happens in our newsgroup, the discussion of many topics
stalls at the freshman level and is regarded as complete in every
detail and nuance. "Physical Electronics," is far in advance of those
thoughts.

Hi All,

This and Myron's reference appear to fill in all the blanks and should
brush away the cobwebs.

What is described above appears to be that of a directional coupler. I
would suspect that the connection between it and the line is through a
capacitor, and the line proximity serves the inductive coupling. I
also presume the "transmission line" was also twin line, otherwise
none of this would work. The action of the directional coupler is
what separates the forward and reflected energies.

I don't know what you are hiding, but some of the ELT (Emergency locator transmitters) are tracked by satellite, and if you set one off sirens go off in control centers.

Great if you are trying to get rescued, a disaster if you want to find your "stash".

Geoff.

Hi Miguel,

Language would have us believe that causal relations "be" from
"cause." Common language sometimes uses "because" as a bridge between
phrases without necessarily implying causality - in other words, the
word "because" is verbal noise when that happens. "Because" is often
a one word reply to a child's question "Why?"

>I believe was you who said dislike representations, if it is yes, were
>you aiming to create mental images of physical phenomena?

Oh, I do that all the time. However, I do not mistake representations
as being the real thing. In other contexts, they are more real than
the real thing. So, if there is dislike, it comes from seeing
inferior representation when better work requires so little more
effort.

Both. But context should resolve that, or it could still be both.
That is why metaphor and analogy are so dangerous. That is also why
it is so useful in fiction. We get enough fiction here.

2.4GHz won't work. It doesn't take much dirt or water to block a
wi-fi signal.

Besides 457Khz avalanche locators, look into Ground Penetrating Radar.
Most operate in the microwave region, but a few models work on very
low frequencies 50-500KHz. FCC Part 19 has a list of acceptable
frequency ranges. If you're tracking gophers, I vaguely recall seeing
an article that described the technology (but am too busy to go
Googling right now).

>the electrons can not do it either. there are not enough of them and
they move too slowly in the plasma to propagate light. these are
easily measured, you can watch the density directly using the ace
satellite web page and calculate the speed of longitudinal waves if
you want, but it won't be anywhere near light speed.

In wire are the sound waves (molecules vibrations) and the electric waves
(electrons vibrations).
The same is in space. There are the acoustic waves and electric waves.

Everybody measure the acoustic. The light (electric waves) speed is known.

If light exsists than there is enough electrons.
Do not tell me that there is the Maxwell material:

That's funny :)

It would be for plotting tunnels from gopher, rabbits, etc. But I don't want to buy COTS, I want to grab all the components myself, put the circuits together on a few breadboards and make my own casing for it.

What's important is finding the simple components needed to implement this type of operation. I've read into ELTs and MELs (Miner Emergency Locator) as well, and while I have found a few circuit diagrams, they did not show what antenna is being used and/or how that was connected to the circuit.

Here is a good example. If I use this oscillator:
http://yhst-27389313707334.stores.yahoo.net/i2c1kto68pro.html
(Voltage adjustable from 1KHz to 68MHz)

If we set this to work off of 1-5KHz:
A) How would I figure out what antenna is needed to send this signal through 10-20ft of dirt and concrete?
B) Where on a circuit would this antenna be attached? (directly connected to the oscillator and 9-12V with perhaps a resistor in-between?)

Good evening (here), to all. I envy most of you for being in Spring...

Cecil I think I understand the notion you have of interaction. It is
on the concept pointed by the word itself (even outside of our radio
context, as shown in your comment about C = A + B) where the
"differences" are laying.
"We" (1) seem to agree with what just explained K1TTT in his last
post. If we could resolve this concept I believe that there would be
fewer differences in the radio discussion. Would you be willing to
try?.
(1) Three or four that are not you, off course :>D

There are other sometimes semi-elusive and possubly tricking concept:
"interference", from my point of wiew this one is other possible
source of differences on our topic.
......
> the only reason you can see standing waves is because a measurement or observation makes them look like they are 'standing' when it is really the interaction of two or more regular traveling waves.

If I do not bad understand your response to Cecil, In your sentence I
would change "interaction" by "manifestation". What do you think?

Side comment: I would say "the only reason we can see (1) 'anything '
of the outside world is by measurement or observation ".
Standing waves are no different in this respect to any other
"external" thing. :>)
(1) Mind vision.

Richard: OK to "representations". Do you think there are things
accesible (or "visible") to our intelect (objectivism) or all we have
are models of external world built by our minds with the help and
mediation of our biological and technical sensing/measurements
apparatus?
I insist in that because I think that two or more models could be
capable to "explain" observed phenomena and we could partially agree
on they instead dispute hard about the "right one" :>)
Metaphysical discussions about the "thing itself" was very strong and
sterile before Newton stop caring about the "whys" and decided dealts
with "howtos" :>). I think you were thinking about this when you
equalize "because"="superstition". Am I right?
However, though causality is an epistemological issue, usually in the
macroscopic phenomena we accept "If A, then B" as a causal relation,
example: If a rock hits my feet I absolutelly think the pain is due to
the stone, not a simple acausal correlation. In this sense is it valid
to use "because the stone")? Thanks to all for your comments

Consider just how big the antenna might have to be at those frequencies.
300,000,000 divided by F in Hz = length in meters.
Using your 5Khz (300,000,000/5000) = 60,000 meters !

That's true. Okay -- I obviously would need a lower frequency to penetrate ground; what would be a workable solution?

What if I took 10ft of antennae and just coiled it so it didn't take up so much space?

Thanks for all the info!

Up here in Alaska, we used to use the SAT Balanced Antenna Tuners to feed
300 Ohm Twin-lead Dipoles, cut for the Lowest Frequency Channel in the
Radio. then use a Bird WattMeter in the Coax Feeding the Tuner, while
doing the Setup. After things were setup for each channel and Band in
the Radio, we would tape a pair of NE2's, one on each side of the
Twin-lead at the closest Voltage Node to the Tuner. then the Operator
could watch the RF Output on the NE2's. worked fair... for the those
days...

no, it is not obvious. where do you draw the line... 1 degree, .1
degree, .001 degree? at what point is the angle small enough to say
that they have 'interacted' and the energy is redistributed?

>
> Did superposition occur in both cases? Yes. Did interference occur in

i propose that 'cancellation' is just a special case of interference
where the waves are 'close enough' to collinear that you never see the
interference pattern. this would of course always apply in a
transmission line because they are confined.

closely analyze the transient response of your non-reflective glass in
the case where the wave is not incident perpendicular to the glass.
do each reflection from each interface separately as the wave travels
in the coating at an angle. then reduce the angle to very near
perpendicular and you should see that there are indeed reflections
that should very nearly 'cancel' each other out as the number of
reflections gets bigger.

Shucks, up there in Alaska, KL7BFB ("Barrel Full of Beer") ran a
(Alaska?) gallon of AM to a lazy H antenna. It had a fluorescent tube
taped to each of the four wire ends, which lit up nicely when he hit the
mike button. Ah, those were the days. . .

'Course I used to run out onto the runway at the Juneau airport to
retrieve ducks I'd shot. Bet you can't do that any more!

I don't remember writing that, Miguel. If I did write that, then I misused the word "interaction". I wrote elsewhere that forward and reflected waves don't interact as long as Z0 stays constant.

I don't know the answer but zero degrees (perfect collimation) will
result in interaction.

> i propose that 'cancellation' is just a special case of interference
> where the waves are 'close enough' to collinear that you never see the
> interference pattern.

When b1 = s11*a1 + s12*a2 = 0 at an impedance discontinuity, wave
cancellation has taken place. s11*a1 and s12*a2 are coherent sine
waves, equal in magnitude, and 180 degrees out of phase. Have you read
the FSU web page where they describe wave cancellation? All these
concepts are old hat to optical physicists.

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/
waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are 180-
degrees ... out of phase with each other meet, they are not actually
annihilated, ... All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ... Instead, upon meeting, the photons
are redistributed to regions that permit constructive interference, so
the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction
of light."

Nope, you sure can't..... Years ago I was servicing an Alascom Alaska Public Fixed Transmitter in Bethel that ran a Full Gallon on 2, 3, 5, & 8 MHz. The Operator I knew from a few years earlier, also was a Ham, and was using one of the OLD Rhombics, From the WWII days, to work the West Coast with 2 watts from a Northern Radio SSB Handheld Prototype on 40 meters. He was said to have the strongest Signal on the band as the sun set each night. They just don't make antennas like those anymore.

At 457KHz they use ferrite rod antennas

I think if you are building your own system you need a crystal locked
transmitter and a very narrow bandwidth (DSP filters ?) receiver in
order to obtain the best range and rejection of unwanted noise and out
of band signals.

Some design notes can be found here.

http://www.ece.uvic.ca/~mblarows/ELEC499/documents/ELEC499A%20Progress%20Report%202-r1.pdf

http://www.backcountryaccess.com/english/research/documents/457andFuture_000.pdf

Google or search US patent websites for 457KHZ transmitter antenna.

Lower frequencies mean longer antenna. :-(
Also since 5Khz is in the audio range of frequencies you might be better
off with a coil based microphone.

> to penetrate ground; what would be a workable solution?

I think you need to do some more research. Its easier not to re-invent
the wheel.

> What if I took 10ft of antennae and just coiled it so it didn't take

If you take any antenna and reduce its physical size you will also
reduce the amount of energy that it can radiate for any given input. I
forget the rule of thumb, but it goes something like inverse square.
Half the radiation quarter of the distance.

agreed. photons are good when working with other elementary particle interactions to represent the em energy lost or transferred during particle interactions. they are not that useful when studying wave propagation or interaction with macroscopic object... including 1/4 wave coatings.

> current.

There seems to be some confusion about the meaning of resistance in
these
posts.

At the start of my electronics education (and I suspect most of
yours), I
was taught that resistance was:
R = V/I

This works for resistors, which have a linear V-I curve which passes
through the origin. This R has the property that it can be used in
R*I^2 to compute the power dissipated in the resistor.

Later in my training, a more sophisticated definition of resistance
was
introduced:
R = deltaV/deltaI
where the V-I curve is not a straight line or does not pass through
the
origin (and some devices even have a negative resistance).
With this, more sophisticated definition of resistance, it is often
not
correct to use R in R*I^2 to compute the dissipation.

It is always correct to compute the dissipation by multiplying the
voltage
by the corresponding current at a particular point on the V-I curve
but
V/I at this point is not the resistance unless the V-I curve is
straight
and passes throught the origin.

The plate V-I characteristic curves for a tube are quite non-linear
and
the use of plate resistance (i.e. deltaV/deltaI) for the computation
of
power is an invalid operation.

V*I of V and I selected at any point on the curve will yield the
power,
but V/I will not be the resistance at this point. You need to dV/dI
for
that.

For those who may be interested, Richard Feynman offers an
introductory
lecture on photons here: http://vega.org.uk/video/subseries/8

It illustrates that attempting to compute 1/4 wave coating behaviour
with photons would be extremely tedious, though possible.

On the other hand, at low light levels, where individual photons
become
discrete events, the wave theory becomes completely inadequate.
Fortunately, for practical applications, power levels are much higher
than this and the wave aproach is quite useful.

If you (and others) will give up on the ridiculous concept of EM wave energy standing still in standing waves, I will not have to refer to photons again. Honor the technical fact that EM forward waves (with an associated ExH energy) and EM reflected waves (with an associated ExH energy) are always present when standing waves are present and that those underlying waves (that cannot exist without energy) are moving at the speed of light in the medium back and forth between impedance discontinuities. Standing waves are somewhat of an illusion and according to two of my reference books, do not deserve to be called waves at all because standing waves do not transfer net energy as required by the definition of "wave". In short, it is impossible for EM waves to stand still.

Quoting one of my college textbooks, "Electrical Communication", by Albert:

"Such a plot of voltage is usually referred to as a *voltage standing wave* or as a *stationary wave*. Neither of these terms is particularly descriptive of the phenomenon. A plot of effective values of voltage, appearing as in Fig. 6(e), *is not a wave* in the usual sense. However, the term "standing wave" is in widespread use."

From "College Physics", by Bueche and Hecht:

"These ... patterns are called *standing waves*, as compared to the propagating waves considered above. They might better not be called waves at all, since they do not transport energy and momentum."

Technically, RF waves *are* light waves, just not *visible* light waves. All the laws of physics that govern EM waves of light also apply to RF waves. That you find it inconvenient for your "mashed-potatoes" theory of energy arguments is not a good reason to abandon the photonic nature of EM waves. It is actually a good reason to keep it in mind and abandon the mashed-potatoes energy arguments as human conceptual constructs that cannot exist in reality. Most of the energy in an EM wave is kinetic energy. Therefore, it cannot stand still.

> There is a wave theory of light, and there is a particle theory
> of light, and these two theories do not play well together.

If they are both correct, they should play well together. If there is any conflict, quantum electrodynamics wins the argument every time.

> While in many situations they will yield the same answers, it
> is not permissible to mix the concepts from each. Distrust
> the conclusions of any exposition which does so.

Actually, distrust the wave theory if it disagrees with QED. Quantum ElectroDynamics has never been proven wrong.

So feel free to prove that standing waves can exist without the underlying component traveling waves traveling at the speed of light in the medium. Feel free to prove that EM wave cancellation does not "redistribute energy to areas that permit constructive interference" as the FSU web page explains. Feel free to prove the Melles-Groit web page wrong when they say such has been proven experimentally. In fact, the interferometer experiment described here proves that reflected EM waves, traveling at the speed of light, exist along with the necessary energy. Take a look at the "non-standard output to screen".

http://www.teachspin.com/instruments/moderni/experiments.shtml

I, personally, am not interested in getting the right answer using the wrong concepts. And I am absolutely sure that your math models do not dictate reality. It is supposed to be the exact opposite.

The impossibility of divergence. That collapsed probability function
can occur in an RF transmission line and in an interferometer.
Secondary effects, e.g. noise, are obviously ignored.

> coming from a 'primer' and containing words like 'somehow' doesn't
> raise my confidence in the explanation.

The "somehow" means that even if someone doesn't comprehend enough to
have "confidence in the explanation", that lack of confidence will
have zero effect on the real-world outcome - the energy involved in
destructive interference wave cancellation will be preserved through
constructive interference based on the conservation of energy
principle. Please feel free to prove them wrong.

Photons are useful for proving that EM waves must necessarily travel
at the speed of light in the medium. Photons cannot stand still -
therefore, EM waves, known to consist of photons, cannot stand still -
therefore any overly-simplified mashed-potatoes version of energy
stored in an RF transmission line violates the laws of physics.

I've no problem with that ! But you do need to look at what work has
already been done by other people and try to understand what problems
they have had to overcome in order to achieve their goal. Then analyse
what you need to do to achieve your goal.

>
> I'm looking for the most lowest level of development that one could

Most entrepreneurs start of with an idea and develop it with very little
resources. But you have to ask the right questions and more important
understand the answers.

Radio propagation through the earth is one of the most challenging
problems you could attempt to solve. You seem to be concentrating on
very low frequencies, fine if you can tolerate very very slow data
flows. I'm sure there are frequencies that will propagate through the
earth fairly easily, but getting to a point where a usable signal
occurs with reliable results isn't easy.

Maybe more information about what you are trying to achieve would help
to point you in a better direction.

Not a loaded question: How do Maxwell's equations applied to a
standing wave prove that the component forward and reflected waves are
moving at the speed of light in the medium? If it can and if I can
understand it, I wouldn't need to use the photon argument.

easy, maxwell's equations don't predict standing waves! they are a
product of superposition and the simplest instrumentation used since
they were first discovered.

Please correct me if I am wrong: If one starts with the (superposed)
standing wave equation, V(x,t) = A*sin(kx)*sin(wt), Maxwell's
equations seem to provide a perfectly valid result (not that I can
recognize perfection). Therefore, how do Maxwell's equations prove
that the component traveling waves necessarily possess a separate
existence? Again, a serious question from an engineer who considers
anything except a logical '0' or logical '1' to be broken. :-)

my differential calculus is a bit rusty, but i don't think that equation satisfies the basic wave equation. from Fields and Waves in Communication Electronics, section 1.14. a solution for the wave equation in a transmission line (or other 1d form) must satisfy the condition that the 2nd derivative wrt x and wrt t equal v-squared... too hard to write in text. but basically take the above and differentiate twice wrt time and twice wrt distance and i don't think you'll get anything that comes out to the velocity squared. the problem is that t and x must be part of the same sinusoid in the F(t-x/v) so that the wave is truly traveling instead of stationary like your equation provides.

in the basic maxwell equations in differential form you also run into the same problem where the curl of the one field is proportional to the time derivative of the other i think you'll end up with a contradiction like k=w if you eliminate the dimensionless terms... i may be wrong on that because its been so long since i've had to deal with them on that level.

That's not true. All the power delivered to an antenna is either radiated or turned into heat -- antennas have to obey the law of conservation of energy like everything else. The fraction which is turned into heat is determined by the loss of the antenna, not its physical size. Loss does generally increase as the size gets smaller, but not by any fixed proportion to the size, and many small antennas can be quite efficient.

On the other hand an EM antenna may not best suit your job. I would
suggest feeding a buried coil and let this be half of a transformer
coupled to your receiver.

It might be worth checking out some of the work done by Bonnie Crystal
KQ6XA and her cohorts. They've been able to communicate from the
earth's surface, down into caves (and back up), using LF and HF radio
systems.

> occurs with reliable results isn't easy.
> . . .

Attenuation through the ground depends on the soil conductivity and dielectric constant, and the frequency. Here's the attenuation in dB/ft for two ground types and a number of frequencies:

Freq MHz	Avg soil(1)	Vy good soil(2)
0.01	0.037	0.091
0.1	0.12	0.29
1	0.35	0.90
10	0.66	2.4
100	0.69	3.3
10,000	0.69	3.4

(1) Conductivity = 0.005 S/m, dielectric constant = 13
(2) Conductivity = 0.03 S/m, dielectric constant = 20

So the distance you can communicate depends on these factors as well as antenna efficiency, power, and receiver sensitivity.

Attenuation in salt water is very much higher, which is why submerged submarines have to communicate at VLF.

> 10 0.66 2.4
> 100 0.69 3.3
> 10,000 0.69 3.4

So if I get this right, a 2.4gHz signal in normal soil would be anttenuated 6.9 db (less than 2 "S units). In very good soil, it would be anttenuated around 34 db, which would make it difficult to receive.

A Pringles can antenna has a gain of about 18db, that would certainly be enough for average soil, and might be good enough for very good soil.

It also has the advantage of possibly being a 2 way link.

for subsurface comms and this sort of application, you typically use a
loop antenna, and accept the terrible efficiency of a physically small
antenna.

Look at the radios used by cavers for communication.

Those dB values are correct for 10 feet of homogeneous soil. Real soil
is stratified, and reflections from layer boundaries could have some
pretty profound effects. 6.9 dB is from 2 to 4 "S-Units" on my Icom,
depending on where on the S meter scale it is.

> A Pringles can antenna has a gain of about 18db, that would certainly be
> enough for average soil, and might be good enough for very good soil.

Relative to what? According to this site
http://www.turnpoint.net/wireless/has.html, a Pringles can antenna
showed about the same gain as a Lucent omnidirectional antenna. Of
course, an 18 dB error is only a mis-estimation of power density by a
factor of 1,000,000,000,000,000,000. Pah, piddly nit-picking details.
You could make it up by increasing the power by the same factor.

> It also has the advantage of possibly being a 2 way link.

A reliable one would take some calculation, planning, and a realistic
idea of antenna performance.

>

Yup. Measure 800V at 0.26A and the power is 208 W. No mention of
resistance. This is good.

From Walt's data indicating 100W and the schematic showing a 5 ohm
cathode resistor, one
might infer that each tube is dissipating (208-100-(5*.26))/2->53.35
W. Feel free to include
the heater and grid dissipations for a more accurate evaluation.

From the 8146B spec sheet, depending on the operating point, Rp (i.e.
slope of plate E-I curve)
is between 10k and 30k so for the two tubes in the circuit it would be
5k to 15k ohms. But this
number is not much use for computing dissipations.

Refering to photons is just fine. Just do not mix them in with wave
theory.

> waves at all, since they do not transport energy and momentum."

All quite orthogonal to the original point, but your point about
standing
waves is quite correct, they are not really waves at all. But your
need
for the reality of underlying waves is quite excessive. The voltage
and

current distribution on a transmission line can be solved with a set
of differential equations which satisfy some boundary conditions.
There
is no mention of forward and reverse waves in this solution. Turns out
though, that the solution can also be factored in to a forward and
reflected wave and this technique will provide the same answer. It
does
not make these waves any more real.

I bring you back to a previous question which you have never
answered...
On an ideal line with 100% reflection, there are points where the
current
and voltage is always 0. Knowing that if either current or voltage is
0,
power is also 0, how does energy cross these point?

And if I cut the line at all the places where the current is zero, it
does not alter the energy distribution on the line one iota. How can
this be if energy is travelling from end to end on the line?

> Technically, RF waves *are* light waves, just not *visible* light
> waves. All the laws of physics that govern EM waves of light also
> apply to RF waves.

PHYSICS has long given up on the idea of waves being an explanation
for light. The wave theory fails miserably when illumination levels
drop to the level that individual photons are being detected.

Though of course the earlier approximate models (waves) are still
useful
when intensity is high enough, just as we still use Newtonian
mechanics
to solve many every-day problems.

You might like to try http://vega.org.uk/video/subseries/8 for an
exposition on the strangeness of photon.

> That you find it inconvenient for your "mashed-
> potatoes" theory of energy arguments is not a good reason to abandon
> the photonic nature of EM waves.

There you go again... mixing up you models. EM waves are analog and in
no way encompass the quantum nature of photons.

> It is actually a good reason to keep
> it in mind and abandon the mashed-potatoes energy arguments as human
> conceptual constructs that cannot exist in reality. Most of the energy
> in an EM wave is kinetic energy. Therefore, it cannot stand still.

There seems to be some misapprehension here. No one has claimed that
EM
waves stand still, though you may have been confused by the word

'standing' in 'standing waves'. But then earlier in your post you
quote
'College Physics' about 'standing waves', so it is not clear where
your confusion originates.

> > There is a wave theory of light, and there is a particle theory
> > of light, and these two theories do not play well together.
>
> If they are both correct, they should play well together. If there is
> any conflict, quantum electrodynamics wins the argument every time.

They are not both correct. QED aligns with many more observations than
does the wave theory. Another reason not to mix them.

> > While in many situations they will yield the same answers, it
> > is not permissible to mix the concepts from each. Distrust
> > the conclusions of any exposition which does so.
>
> Actually, distrust the wave theory if it disagrees with QED. Quantum
> ElectroDynamics has never been proven wrong.

And the wave theory does disagree with QED at low levels, while at
higher illumination levels QED agrees with the wave theory.

And yet known of this aligns with the photons being part of the wave
theory of light. They two theories remain distinct.

For all involved in the thread -- here's a perfect example. Sondes are locator systems used in many areas (I think) such as pipelines: http://www.rjmcompany.com/Pipe-cable-locator-RD2000-SuperCAT.htm

These have frequencies of 512hz, 8Khz and 33Khz

I'm searching for any specs now regarding crystal and antenna for both transmitter and receiver. But I'm certain that the antenna isn't 1000's of meters long ;)

If I'm reading this right -- I would want to build my own version of the technology rather than purchase theirs'.

I have an old '58 copy of the ARRL handbook, and page 534 has the
"Twin-Lamp" tuning indicator for balanced line. It consists of a
couple of low-voltage flashlight bulbs wired to a short piece of
balanced line to insert into the transmission line.

Solder the tips of two flashlight bulbs together, wire that tip joint
to the short length of balanced line, and wire the bulb shells to the
line, too. Insert the device into the transmission line for tuning.

Fire things up. For minimum SWR, the bulb nearest the transmitter will
be bright, the bulb nearest the antenna will be dark. Or if the two
bulbs are glowing with the same brilliance, you have high SWR.

Good grief, I have answered that question at least a dozen times. The
net current being zero is just an illusion caused by superposition of
two magnetic fields propagating in opposite directions that are equal
in magnitude and opposite in phase. The two traveling waves keep on
trucking at their relatively constant ExH energy levels in opposite
directions. If you want to account for the energy, when the current is
zero, all of the energy existing at that point is in the electric
field and, sure enough, the voltage is at a maximum at that point-
duuuhhhh again. There is absolutely no point on an active transmission
line where the net energy level is zero. Again, you guys are never
going to convince anyone that the Golden Gate Bridge doesn't need
maintenance because the net traffic on the bridge is zero. How the
heck can thousands of vehicles traveling one direction while the same
number of vehicles are traveling in the opposite direction add up to
zero effect in reality? Please get real.

> And if I cut the line at all the places where the current is zero, it
> does not alter the energy distribution on the line one iota. How can
> this be if energy is travelling from end to end on the line?

As I told you years ago, when you cut the line, you radically change
the impedance and create a reflection that didn't exist before you cut
the line. Hint: There are no reflections at a point of constant Z0.
There are only reflections at an impedance discontinuity. The
alteration of the energy distribution (to which you seem to be blind)

can easily be observed in a TV system.

> PHYSICS has long given up on the idea of waves being an explanation
> for light.

And RF waves are technically light, just not visible light. When I was rummaging through the Texas A&M library, I found a book entitled, "Light". It covered the subject of RF waves.

> EM waves are analog and in
> no way encompass the quantum nature of photons.

You could become famous if you can prove that EM waves are not quantized. Good luck on that one.

> No one has claimed that EM waves stand still, ...

Please prove your ridiculous assertion that no one has ever claimed that EM waves can stand still.

My calculus is probably a lot rustier than yours but it would be very important for this discussion if Maxwell's equations do not work for the standing wave equation. That would essentially prove that the mashed-potatoes theory of transmission line energy is bogus.

I built one of those things in the 50's. I was feeding a resonant
1/2WL 40m with 1/2WL of TV twinlead. I could never get the reflected
bulb to go dim, no matter what I did, because 300/50 = an SWR of 6:1.
My reflected power was more than 1/2 of the forward power. It was only
four years later as I got close to a EE degree, that I understood why
the reflected bulb would never go dim. :-)

Hi Keith,

Each tube is dissipating 53.35W? What a fire-eater! Each tube in an
RF application is rated for between 18W to 35 Watts maximum. However,
those maximum values are continous service, not tune up. Further, Ham
usage with long duty cycles would average the plate dissipation over
the long haul to well below 50+ W.

When I review the RCA specifications for a 6146B, published Feb 1964,
I find that both Walt's Plate voltage and Plate current exceed
absolute maximum ratings of (depending upon service) 750V at 250mA.
However, this would seem to be tolerably within generous meter
inaccuracy (if I were to peg it as low as 5%). Also, the 250mA meter
mark is an ad-hoc adjustment set at a condition of maximum power, not
by independantly confirming the actual current. That is of little
consequence to me and Walt's numbers arrived at straight from the
Kenwood service manual are suitable.

However, when we return to the "dissipation," through both RF and
Heat; then we are very close to the classic 50% efficiency of a
matched (by Conjugate Z basis) source.

The heat from the plates satisfy every physical interpretation of a
classic resistor, and an ordinary Ham transmitter exhibits what is
classically called source resistance.

****

So far, all of Walt's data and extrapolations of R are right on. I have seen similar reports through alternative methods seeking the same determination that agree. However, I don't see how he then jumps the tracks to hedge R not being real and being borne by the plate of the tube.

Keith, I measured 1400 ohms at the input of the pi-network. The output power was 100 w at 50 ohms, meaning an output voltage of 50 v and current 1.414 a. The ratio of output to input resistances of the pi-network is 28, meaning the voltage at the network input is 374.17 v. Thus, neglecting the small loss in the network, the input current to the network is 0.267 a. and the power entering the network is 100 w.

I prefer to consider the source resistance of the power amp to be at the output of the network, which, when adjusted to deliver 100 w into the 50 + j0 load, the source resistance is 50 ohms. On the other hand, if you wish to consider the source resistance at the input of the network, then it's 1400 ohms, not somewhere between 5k and 15k ohms.

Consequently, if Rp is between 5k and 15k, Rp cannot be considered the source resistance of the amp. From this info I still believe that Rp is not the source resistance of an RF power amp.

I understand that the efficiency of the amp is determined by the difference between plate power input output power, which is the power lost to dissipation in the plate that is 108 w in the example I presented. Efficiency does not include filament and grid powers.

Richard, perhaps our disagreement on Rp is only in a misunderstanding concerning 'real'. Contrary to what you believe I said, I consider resistance Rp as real, but not as a resisTOR. And even though 'real', Rp is non-dissipative, and therefore does not dissipate any power--it only represents power that is not developed in the first place by causing a reduction of the plate voltage developed across the load current increases--so how could it be 'source' of the power delivered to a load? In the absence of Rp the output power would be greater by the amount lost by the presence of Rp.

Hi Walt,

The physical plate is in series with the load, the physical plate conducts the current in the load, the physical plate and the load both dissipate equal amounts of heat. I would presume the load is a physical resistor just as the physical plate is a resistor.

Is that load resistor dissipating power?

For your logic to be consistent, then the dummy load does not dissipate power, because it dissipates heat identical in amount and by the same physical, atomic process as steel.

If you are saying the physical plate is not a "carbon" resistor, then that is exceedingly specific and wholly original requirement that I doubt you could cite any authority demanding. It would exact that only the metal carbon qualifies and the metal steel does not when it comes to source resistance.

As I already know that there are no references available for you to cite, and this unique qualification is original to you, as your hypothesis you have to defend it with data.

Where to begin?

This might shed a little light on the discussion.

Consider a diode, forward biased by a 10 mA DC current source connected directly across it. The characteristics of this particular diode are such that the voltage is exactly 0.7 volt.

What's the resistance of the diode?

Is the diode's resistance V/I = 0.7/.01 = 70 ohms? Well, yes. The diode is dissipating power, equal to V*I = 7 mW. If we removed the diode and replaced it with a 70 ohm resistor, the voltage and current would be exactly the same as before, and the resistor would dissipate exactly as much as the diode. If the resistor's resistance is 70 ohms, then the diode's resistance is surely 70 ohms also.

Is the diode's resistance "non-dissipative"? No, it dissipates exactly as much as the equivalent resistor.

Now connect another current source across the biased diode, but make it an AC source and connect it through a capacitor. Make the AC source current 0.1 mA RMS, which is much less than the bias current of 10 mA. What AC voltage should we expect? Well, it's not 0.1 mA * 70 ohms, because 70 ohms is the DC resistance V/I, and the AC current is encountering a resistance of dV/dI, where dV/dI is the ratio of the *change* in voltage to the *change* in current. This is the dynamic, or AC resistance, and it equals the slope of the V/I curve of the diode. The AC and DC resistance are the same for a simple resistor, but not the nonlinear diode. The dynamic resistance actually changes for each instantaneous value of the AC waveform, but as long as the AC current waveform is much less than the DC bias current, the change won't be much. It turns out that the AC resistance for a diode is about 0.026/Idc where Idc is the bias current. So in our case, the AC resistance is about 0.026/0.01, or about 2.6 ohms. Therefore we'd see an AC voltage across the diode of 0.1 mA * 2.6 = 0.26 volt.

The AC voltage is in phase with the AC current through the capacitor, so the AC current source is supplying power to the diode, an amount equal to Iac * Vac = 0.1 mA * 0.26 V = 0.026 mW. What happens to this power? The answer is that the diode turns it into heat. Is the AC resistance "dissipative"? Of course it is, it's dissipating the AC power supplied by the AC current source. As before, we can replace the resistance, this time the AC resistance, with a resistor -- we'll just have to connect it through a capacitor so it doesn't see any of the DC bias. Now the equivalent diode is a 70 ohm resistor with another 2.6 ohm resistor in parallel through a capacitor. This will behave just the same as the diode, with respect to voltage, current, and power dissipation, both AC

and DC, at the specified operating point.

The lengthy discussion about tube plate resistance has muddled the DC operating point (equivalent to the diode DC bias) and the plate resistance, which is the plate's AC or dynamic resistance. They're related just the same as for the diode. And just like the diode, if you were to send an AC signal to the plate of a biased tube through a capacitor, you'd find an AC voltage and current which are in phase resulting in power being delivered to the tube, and an increase in plate dissipation in the amount of that power.

Hi Walt,

If I simply look at the spec sheet for the 6146, and note that in push-pull it has a plate-to-plate Load Resistance of 3600 Ohms to 6050 Ohms (depending upon many variables); and if I simple reconfigure the two tubes from series to parallel; then the Load Resistance falls somewhere in the range of 900 Ohms to 1500 Ohms.

I am having a hard time trying to tease out how you would explain that the plates do not dissipate their half of the power when your numbers demonstrate every conventional expectation of literal and physical source resistance.

Do you have data for the peak-to-peak voltage swings at the grid and plate for the final?

I think we need to know a bit more about your application.

I have one of these pipe / cable locators, you need to have a good idea of the route the pipework its taking and then 'sweep' the approximate area with the end of the locator. If you don't have a starting point it's very time consuming to cover a large area.

The avalanche beacon permits initial detection over a much wider area which considerably speeds up a 'blind' search.

What size transmitter (physical) are you able to use, Max weight, Battery duration, required detection radius, depth of burial etc.

Hello,

my mobile setup is composed by a 2 meter vertical whip feeded immediately close to it by an automatic antenna tuner.

My poor knowledge of antenna systems think that the ATU, choosing the appropriate LC value, bring the entire system in a resonant condition: true or false ?

And , second question, because a friend of mine own a MFJ 269 analyzer, how i can *approximately* have an idea of the efficiency on a frequency F for my whip ?

Thanks in advance,

The tuner will provide an impedance match to your transceiver (50 ohms). It won't make your antenna resonant on 20m (or any other band, other than 2m).

Hello, and that's sort of the ultimate goal. The tuner is designed to match the antenna type(s) to the source (transmitter) and transmission line design (characteristic) impedance.

> And , second question, because a friend of mine own a MFJ 269 analyzer, how
> i can *approximately* have an idea of the efficiency on a frequency F for my
> whip ?

The problem here is an impedance analyzer can't distinguish between resistive losses (antenna, ground, tuner (if considered part of the antenna)) and the radiation resistance of the antenna. To determine efficiency you'd have to make some field strength measurements (usually performed with a calibrated field strength meter) in order to determine how much of the power going into the antenna terminals is being radiated into free space. The only "approximation" would be to measure the resistive part of the antenna feedpoint impedance and then subtract from this the radiation resistance obtained from calculation. Sincerely, and 73s from N4GGO,

If you perform a frequency sweep with an antenna analyzer connected to
the tuner input and the impedance goes from R-jX ohms to 50+j0 ohms to
R+jX ohms, the purely resistive frequency meets the definition of the
system resonant frequency. Unfortunately, under those extremely
lossy conditions, "system resonance" means almost nothing.

I think "CQ" meant the whip was 2 meters long. That would be 1/4 wave
on 38 MHZ if I did the math right. This is the 8 M band? The tuner
might get it on 20 M, but 40 M will be a stretch.

Every? A classis resistor satisfies the equations
R = V/I = deltaV/Delta/I
Given the V/I curves published for the 6146B, I see no reason to
expect
the plate resistance to satisfy these two equations.

But what exactly do you mean by 'real'?
R=V/I?
R=deltaV/deltaI?
Heat is dissipated?

The relationship is so close, I would suggest that the Sonde is a perfect application for my needs.

Like I said previously, I want to build my own version. So we'll assume this as the target technology leaving me with the question of what antenna would be needed to perform these operations. I suppose the oscillator is just a simple crystal or perhaps even voltage controlled (adjustable). I can use a 555 for this....

I think we need to know a bit more about your application.

I have one of these pipe / cable locators, you need to have a good
idea of the route the pipework its taking and then 'sweep' the
approximate area with the end of the locator. If you don't have a
starting point it's very time consuming to cover a large area.

The avalanche beacon permits initial detection over a much wider area
which considerably speeds up a 'blind' search.

What size transmitter (physical) are you able to use, Max weight,
Battery duration, required detection radius, depth of burial etc.

Miguel, do you fully realize the importance of Maxwell's equations
being nonfunctional with the equation for standing waves? It means
that any analysis based entirely on standing waves is probably invalid
in some area of the analysis - probably including Keith Dysart's
latest postings about the standing wave's zero current being
meaningful in some way.

>easy, maxwell's equations don't predict standing waves! they are a
product of superposition and the simplest instrumentation used since
they were first discovered.

"Kundt's tube is an experimental acoustical apparatus invented in 1866 by
German physicist August Kundt[1][2] for the measurement of the speed of
sound in a gas or a solid rod. It is used today only for demonstrating
standing waves and acoustical forces."

Heaviside wrote "Maxwell" equations" much later.

EM waves are the angular waves in the solid body. It would not be easy to
instal the mirror in such body.

You do not know that EM waves were stripped away in 1864.
The Maxwell's math is used in machinery to calculate the torsion vibration.
Maxwell predicted it:

"I propose now to examine magnetic phenomena from a mecha nical point of
view, and to determine what tensions in, or motions of, a medium are capable
of producing the mechanical pheno mena observed. If, by the same hypothesis,
we can connect the phenomena of magnetic attraction with electromagnetic
phenomena and with those of induced currents, we shall have found a theory
which, if not true, can only be proved to be erroneous by experiments which
will greatly enlarge our knowledge of this part of physics."

The hipothesis " be proved to be erroneous by experiments" but we have the
excelent math for thr solid body.

Maxwell's equations are for angular waves in the solid body.
The transmission line and ends of it (antenna) are exactly like the Kundt's
tubes. In the wires is the electron gas.

Another fine example is a "negative resistance" device like a tunnel diode, gas discharge tube (neon bulb), or a free burning arc.

Obviously, the arc dissipates power, but the V/I slope is negative.

presuming you mean your whip is 2 meters long (not tuned for the 2 meter band, and only 50 cm long)

On 40m? Maybe, maybe not. people have used a light bulb as an antenna.

It will almost certainly be inefficient. Here's a short description (filled with technical detail errors, which will no doubt provoke a long discussion)..

All antennas have a property called "radiation resistance" (smaller antennas have smaller radiation resistances)
All antennas also have resistive losses.
There are also losses "after the wave has left the antenna" (e.g. ground reflections, etc. why salt water marshes are prized for vertical pol).
The latter are not considered here.

To a first order (back, all you nit pickers.. first order), the power from the transmitter gets distributed between the radiation resistance and the loss resistance. So, the "efficiency" can be thought of as that fraction of power that winds up in the radiation resistance, as opposed to in the loss resistance.

Important here: if the radiation resistance is low, that doesn't mean poor efficiency: as long as you keep the resistive losses low too.. which can be a challenge (assuming you're not carrying a vat of liquid helium, for instance).

Part of the problem is that the resistive losses aren't just in the antenna, but also in any substance which is immersed in the antenna's electric and magnetic fields (like the steel of your car, and the not particularly good conductivity, but not a perfect insulator either, soil under the car).

And, then, there are losses in how you get from Tx to Antenna. If your antenna presents an impedance that is not what the transmitter is providing, you've got to transform it somehow, typically using Ls and Cs, etc. (in your autotuner). Those components also have some amount of loss, although I'll bet it's less than 10% in most situations (otherwise, the tuner/matching network would melt, and they don't)

Moral of story..
radiation resistance doesn't drop much from a full size antenna until you get around 1/10th wavelength, then it starts to drop real fast (as length squared)

For a dipole:
L/lambda = 1/2, R= 73 ohms
L/lambda = 1/5, R = 8
1/10, 2
1/20, 0.5
1/50, 0.08
1/100, 0.02

On 40m, your 2m long whip is like a 4m long dipole: 1/10 (in the above table) for 2 ohms. Since it's a monopole, it's actually half.. 1 ohm..

That's pretty low..

A bunch of people have measured loss resistances for typical mobile installations and they get numbers in the 10-20 ohms range, so you're looking at an efficiency of about 10% of what you'd get with a full sized 10m tall vertical.
(this isn't far off the "mobile antenna is a 6dB hit" empirical observation)

I'm assuming here that somehow you'll be able to match the 50 ohms in the feed line to the 10-20 ohms with a lot of reactance at the feedpoint without too much loss (a reasonable assumption)

> 73s from N4GGO,

A good deal of, if not the majority of, the loss in a short antenna system is in the matching system components. So even if this method allowed you to get a reasonable estimate of the efficiency of the antenna itself(*), you still wouldn't know what fraction of the transmitter power is getting radiated, since you can't tell how much is lost in the tuner.

(*)My limited experience in doing careful antenna measurements leads me to be very skeptical of the ability to determine antenna efficiency even very roughly by a single impedance measurement. I think comparison of measured bandwidth to lossy model results is probably the best indicator.

The bottom line is that the impedance meter won't tell you much about the efficiency of the antenna or system. About the only practical way available to most amateurs is comparison of received signal strengths between the antenna and a known reference antenna, using a step attenuator to measure the difference.

Hi Roy,

That is a good analogy of power, non-linearity and dynamic resistance.

As for the DC operating point being muddled into the discussion, I
don't think I have seen anyone raise that separately - which is
perhaps what you mean.

For Walt, and all,

So, to take that part, and give this RF final stage a better view of
the dynamic resistance's part in source resistance, let's consider how
much power is dissipated in the plate that is strictly due to the bias
and a zero input condition.

There are few typical characteristics that match Walt's data, and I
have to abstract both from the TS520S schematics, service manual, and
the published data for the 6146B for this. As I had to juggle these
considerations to give Walt some perspective of the plate resistance
being far lower than his anticipated 5 kOhm to 14 kOhm, so I must
similarly reckon for the DC baseline.

By all things considered, we have a grid one bias of -60V. This
exceeds the RCA published data for class AB, but not for C (which is
in excess of this at -100V or more). My readings of all these
variables puts the plate current for a zero input at 20-25-30mA which
yields from something under 20W to something over 20W for a plate heat
load. Subtract this from the 53+W Keith figured and we have a ball
park 30W heat load attributable to RF. This is a back of the napkin
kind of balance sheet, mind you. I say this because the drive has a
cooling factor in that it drives down that zero input plate current
during part of a cycle. Having said that, it is enough to simply note
that there is significant heat dissipated in the plate that is
attributable to the RF current that passes through it and the load.

Richard, you ask me where to begin. Well, I begin with Terman, where I quote him in Chapter 19, Sec 19.3, in Reflections 2. Since attachments are prohibited in this forum I'm going to try to copy Sec 19.3 here, which explains in detail why plate resistance Rpd is dissipative, while Rp is non-dissipative--it explains the difference between the two. In addition, I don't believe the diode is a correct model for describing the operation of a Class B or C amplifier. Now the quote:

Sec 19.3 Analysis of the Class C Amplifier

The following discussion of the Class C amplifier, which reveals why the portion of the source resistance related to the characteristics of the load line is non-dissipative, is based on statements appearing in Terman’s Radio Engineers Handbook, 1943 ed., Page 445, and on Terman’s example of Class C amplifier design data appearing on Page 449. Because the arguments presented in Terman’s statements are vital to understanding the concept under discussion, I quote them here for convenience: (Parentheses and emphasis mine)

1. The average of the pulses of current flowing to an electrode represents the direct current drawn by that electrode.
2. The power input to the plate electrode of the tube at any instant is the product of plate-supply voltage and instantaneous plate current.
3. The corresponding power (Pd) lost at the plate is the product of instantaneous plate-cathode voltage and instantaneous plate current.
4. The difference between the two quantities obtained from items 2 and 3 represents the useful output at the moment.

5. The average input, output, and loss are obtained by averaging the instantaneous powers.
6. The efficiency is the ratio of average output to average input and is commonly of the order of 60 to 80 percent.
7. The efficiency is high in a Class C amplifier because current is permitted to flow only when most of the plate-supply voltage is used as voltage drop across the tuned load circuit RL, and only a small fraction is wasted as voltage drop (across Rpd) at the plate electrode of the tube.

Based on these statements the discussion and the data in Terman's example that follow explain why the amplifier can deliver power with efficiencies greater than 50 percent while conjugately matched to its load, a condition that is widely disputed because of the incorrect assumptions concerning Class B and C amplifier operation as noted above. The terminology and data in the example are Terman's, but I have added one calculation to Terman's data to emphasize a parameter that is vital to understanding how a conjugate match can exist when the efficiency is greater than 50 percent. That parameter is dissipative plate resistance Rpd. (As stated earlier, dissipative resistance Rpd should not be confused with non-dissipative plate resistance Rp of amplifiers operating in Class A, derived from the expression Rp = delta Ep/delta Ip.)
It is evident from Terman that the power supplied to the amplifier by the DC power supply goes to only two places, the RF power delivered to load resistance RL at the input of the pi-network, and the power dissipated as heat in dissipative plate resistance Rpd (again, not plate resistance Rp, which is totally irrelevant to obtaining a conjugate match at the output of Class B and C amplifiers). In other words, the output power equals the DC input power minus the power dissipated in resistance Rpd. We will now show why this two-way division of power occurs. First we calculate the value of Rpd from Terman's data, as seen in line (9) in the example below. It is evident that when the DC input power minus the power dissipated in Rpd equals the power delivered to resistance RL at the input of the pi-network, there can be no significant dissipative resistance in the amplifier other than Rpd. The antenna effect from the tank circuit is so insignificant that dissipation due to radiation can be disregarded. If there were any significant dissipative resistance in addition to Rpd, the power delivered to the load plus the power dissipated in Rpd would be less than the DC input power, due to the power that would be dissipated in the additional resistance. This is an impossibility, confirmed by the data in Terman's example, which is in accordance with the Law of Conservation of Energy. Therefore, we shall observe that the example confirms the total power taken from the power supply goes only to 1) the RF power delivered to the load RL, and 2) to the power dissipated as heat in Rpd, thus, proving there is no significant dissipative resistance in the Class C amplifier other than Rpd.

Data from Terman's example on Page 449 of Radio Engineers Handbook:

(1) Eb = DC Source Voltage = 1000 v.
(2) Emin = Eb - EL = 1000 - 850 = 150 v. [See Terman, Figs 76(a) & 76(b)]
(3) Idc = DC Plate Current = 75.l ma. 0.0751a.
(4) EL = Eb - Emin = 1000 -150 = 850 v. = Peak Fundamental AC Plate Voltage
(5) I1 = Peak Fundamental AC Plate Current = 132.7 ma. 0.1327 a.
(6) Pin = Eb x Idc = DC lnput Power = l000 x O.0751 = 75.l w.
(7) Pout (Eb - Emin)/2 = ELI1/2 = Output Power Delivered to RL = [(1000 -150) x 0.1327]/2 = 56.4 w.
(8) Pd = Pin - Pout = Power Dissipated in Dissipative Plate Resistance Rpd = 18.7 w,
(9) Rpd = 18.7W/0.0751^2 = Dissipative Plate Resistance Rpd = 3315.6 ohms
(10) RL = (Eb - Emin)/I1 = EL/I1 = Load Resistance = 850/0.137 = 6405 Ohms (6400 in Terman)
(11) Plate Efficiency = Pout x 100/Pin = 56.4 x 100/75.1 = 75.1%

Note that Terman doesn't even mention non-dissipative plate resistance Rp, and therefore it cannot be considered the source resistance.
Note also in line (10) that RL is determined simply by the ratio of the fundamental RF AC voltage EL divided by the fundamental RF AC current I1, and therefore does not involve dissipation of any power. Thus RL is a non-dissipative resistance. (For more on non-dissipative resistance see Appendix 10.)
Referring to the data in the example, observe again from line (10) that load resistance RL at the input of the pi-network tank circuit is determined by the ratio EL/I1. This is the Terman equation which, prior to the more-precise Chaffee Fourier Analysis, was used universally to determine the approximate value of the optimum load resistance RL. (When the Chaffee Analysis is used to determine RL. from a selected load line the value of plate current I1 is more precise than that obtained when using Terman’s equation, consequently requiring fewer empirical adjustments of the amplifier’s parameters to obtain the optimum value of RL.) Load resistance RL is proportional to the slope of the operating load line that allows all of the available integrated energy contained in the plate-current pulses to be transferred into the pi-network tank circuit. (For additional information concerning the load line see Sec 19.3a below.) Therefore, the pi-network must be designed to provide the equivalent optimum resistance RL looking into the input for whatever load terminates the output. The current pulses flowing into the network deliver bursts of electrical energy to the network periodically, in the same manner as the spring-loaded escapement mechanism in the pendulum clock delivers mechanical energy periodically to the swing of the pendulum. In a similar manner, after each plate current pulse enters the pi-network tank curcuit, the flywheel effect of the resonant tank circuit stores the electromagnetic energy delivered by the current pulse, and thus maintains a continuous sinusoidal flow of current throughout the tank,

in the same manner as the pendulum swings continuously and periodically after each thrust from the escapement mechanism. The continuous swing of the pendulum results from the inertia of the weight at the end of the pendulum, due to the energy stored in the weight. The path inscribed by the motion of the pendulum is a sine wave, the same as at the output of the amplifier. We will continue the discussion of the flywheel effect in the tank circuit with a more in-depth examination later.

Let us now consider the dissipative plate resistance Rpd, which provides the evidence that the DC input power to the Class C amplifier goes only to the load RL and to dissipation as heat in Rpd (Again, not Rp.) With this evidence we will show how a conjugate match can exist at the output of the pi-network with efficiencies greater than 50 percent. In accordance with the Conjugate Matching Theorem and the Maximum Power-transfer Theorem, it is well understood that a conjugate match exists whenever all available power from a linear source is being delivered to the load. Further, by definition, RL is the load resistance at the tank input determined by the characteristics of the load line that permits delivery of all the available power from the source into the tank. This is why RL is called the optimum load resistance. Thus, from the data in Terman’s example, which shows that after accounting for the power dissipated in Rpd, all the power remaining is the available power, which is delivered to RL and thence to the load at the output of the pi-network. Therefore, because all available deliverable power is being delivered to the load, we have a conjugate match by definition. In the following Sec 4 we will show how efficiencies greater than 50 percent are achieved in Class C amplifiers operating into the conjugate match.

Thanks to all

Hey boys! (Cecil, David, Michael, et al) It is very funny and
entertaining, I enjoy your postingss mostly in "read only" mode
because translate not simple mine ones still being a struggle for
me :-)
....
Cecil, I never studied standing waves with Maxwell equations (except
in usual examples of cavity resonators cases learning classes), I
studied only classic electric differential solution to the
telegraper's equations.

Hi Keith: We tend to think of energy as a "tangible and real" easely
intuited thing "out there" (as a water or horses) but we must not
forget energy is a really elusive CONCEPT devised to explain changes
in physical systems. Familiarity tend us to fetishize concepts, then
we easily can get caught in troubles type => "Where velocity goes when
the car smash?" :-D :-D. We must be carefully with forces, powers,
velocities, etc. in this sense...
Note how Terman prudenty deals with differential solution of
Telegrapher's equations: "This combinatiosn of voltage and current can
be INTERPRETED as a wave train traveling toward receiver" (1)
(capitalized letters by me).

The very term "standing waves" leads to endless Ham controversies
about concept of "wave" word in our context.(wave as "a disturb that
propagates" and wave as pattern-figure-graphics-representation of
interference pattern of voltage/current measured along the TL). This

"wave pattern" (is it correct to write "wavy" pattern?) do not carry any energy from one place to another on the TL it is not a "wave" in the other sense (transport phenomena). What do you think?

Can I use any wire or does it have to be a certain kind?

I've asked about coiling wire but I didn't get any positive feedback.
However, it wasn't described as impossible.

Plate Efficiency = 48%

By all reckoning according to your reference from Terman, using what
you report, it appears that you have exhibited a Conjugate basis Z
match as you claim, and that the plate Rpd by the same reckoning is
the same as we formerly arrived at Rp. It would appear that over the
course of some dozen years between publications that Terman simplified

the term Rpd to Rp which, according to you, is not found in your volume, and as such this migration of terms seems logical by the numbers agreeing in both volumes for different labels. Inasmuch as Rpd does not appear in Terman's later work, nor in any of the Tube specifications since that era, Rpd appears to be an orphan.

You report your own Rp (now Rpd) or its equivalent by resistor substitution (a valid determination) to be on order of 1400 Ohms. This conforms closely to the value found above, and the data reported by RCA for Rp in a design of similar characteristics. The range of possible values taken from RCA: 900 Ohms to 1500 Ohms.

Taking your low, the high from my range, and the higher computed through your supplied data using Terman's formula, the average is 1500 Ohms with a variation of roughly 6% which is about the limits of superlative accuracy for conventional bench equipment. What this means is that all three values are identical on the basis of accumulation of error.

Having said that, this is not the end of analysis. However, at the first pass your data has demonstrated that the Plate serves as a real resistor dissipating half of the available power being supplied to a load that is conjugately matched.

The only difference is that you state as much, but dismiss the plate dissipation as being a real resistor. Perhaps I mis-state you. If not, I take issue with that and ask once again, as this perception is unique to your hypothesis, do you have data that differentiates the resistance of steel absorbing and dissipating the impact of the electron stream as being different from carbon absorbing and dissipating the impact of the electron stream?

Would it serve to replace the steel plate with a graphite one like the 845 (similar to the GM-70)? When I review the spec sheets for this tube, it reports an Rp of 1700 Ohms - hardly remarkable at 100 more Ohms than the computation above. Of course, there are compounding application differences, but still, graphite plates or steel don't seem to force a new conclusion. Materials don't seem to be an issue.

Certainly the mechanisms of resistance differ in the kinetics of speed, but not in the product of heat. To my knowledge, no authority bases the concept of resistance upon the speed of the electron, but rather in the kinetics of its collision.

Richard, I'm totally shocked by what I've read above. I can't believe it! I can't believe you've distorted what I've written in my last post above to the extent that I can't possibly clarify or correct it--it's more than just misunderstanding. In addition, it's totally misleading to other readers of this thread, and makes me appear as a moron and an idiot.

Sorry, Richard, I'm through with this thread. There's nothing I can do now to fix the situation.

Walt, W2DU

I checked this out one time and my memory is a bit hazy. Using my
computer program which ofcourse could have a glitch in it, I found
that the gain hit a max at the very low resistance value and then
backed off as the resistance became close to zero. This blip occurred
during the last fraction of an ohm
just prior to closure of supplying gain figures.
At the time I put this down as the point where the skin depth
penetration was minimal and thus we had reached a point where the
applied current was totally to provide gain after which it dropped
dramatically. I looked at this as a progression for the current flow
in the surface of the element where it progressed to the surface and
the flow
progressed above the surface but below the particle encapsulation.
Further progression created losses and thus the gain blip dropped.
Resistance never dropped to zero thus ohms law
was not declared invalid. If somebody could duplicate the above via
another program it may prove interesting. Keep- dropping the applied
frequency until you reach about 0.7 ohms and then start recording.

It's possible.. But feeding a whip with a tuner usually does not
make
for an efficient mobile antenna. Not only are many/most tuners more
lossy than say using a loading coil on the whip, but current
distribution
suffers. Maximum current will be at the tuner which is not desirable.
The location of the loading coil has a large effect on the current
distribution
and efficiency of the antenna. Where you have it is about the worst
possible
place. :(
I have lots of people ask me about running whips matched with tuners..
I pretty much have a standard reply.. No! Not on my watch!
Chortle..
My mobile antenna is center loaded in the driving config.. Even higher
if
I add the 3 foot lower mast, but that's only when parked. In the
parked config,
my loading coil is 8 ft above the base of the whip. "14 ft tall whip"
And yes, you can tell a pretty good difference from the normal driving
config,
with the coil at 5 ft above the base. "11 foot tall whip"

I'm happy to see that Roy posted this clarification about dynamic versus static resistance. I haven't read all the posts here, but those others that I have seemed to completely skirt the issue of the meaning of "plate resistance."

Further to Roy's posting, though, you must realize that a device with more than two terminals is complicated by the fact that you need to specify that the dynamic resistance is measured with other terminals held constant. So, for example, plate resistance of a tube is normally defined as the partial derivative of plate voltage with respect to plate current, with the grid-to-cathode voltage held constant, and of course at some particular plate voltage (and corresponding current). For a tetrode, the screen-to-cathode voltage must also be constant.

The reason for this is that you will get completely different answers if you don't hold the voltage of the grids constant with respect to the cathode. For example, if you set up a circuit with a tube with the grid grounded, and an appropriate resistor between the cathode and ground (not bypassed), to establish a desired bias point, then a change in plate current will be accompanied by an essentially identical change in cathode current, and a corresponding change in drop across the cathode resistor, which represents a change in grid-to-cathode voltage. Measuring dV/dI at the plate in such a circuit will yield a much higher resistance than if the grid-to-cathode voltage is kept constant. It is, in fact, a good way to make a constant current source.

There is no particular relationship that must be maintained between the load resistance you present to an amplifier element -- a tube or a bipolar transistor or a FET -- and the plate/collector/drain (dynamic) resistance of the device. For example, it's common to operate a push-pull pair of 6146's in audio service with a load around 5000 ohms (plate to plate) at 500V plate supply voltage, 185V screen voltage, and perhaps 30mA plate current. That's effectively 2500 ohms to each plate of the pair. But at that operating point, the plate resistance of a 6146 is around 600V/30mA, or 20k ohms (roughly, from plate characteristic curves in my old RCA transmitting tubes manual). On the other hand, a triode will have a much lower plate resistance, likely similar to the load resistance--but again, not really related to it.

Another rather interesting thing happens, though, when you connect an RF load through a tank circuit such as a PI network. It's quite possible for a pi network to transform a 50 ohm RF load so it presents a reasonable (say) 4k ohm RF load to the plate of a tube like a 6146. But that same pi network will in turn transform the plate resistance--or rather, the net impedance of the tube in its particular circuit configuration (grounded grid or grounded cathode, and invariable some amount of feedback whether you wanted it or not), along with the DC feed (RF choke) in parallel, to quite possibly an impedance not very close to 50 ohms, and likely rather reactive. I can, without much difficulty, design a PI network that will yield a source resistance at the output connector that's a lot less than 50 ohms, using a tetrode amplifier tube, while giving a very decent transformation of a 50 ohm load to a desired load at the plate of the tube.

And as if that weren't enough, I can modify the output impedance further by application of feedback; this is more commonly done at audio frequencies, where amplifiers designed to drive loads like 4 ohms an 8 ohms have output impedances in the area of a small fraction of an ohm. But it's also done with RF amplifiers, often for reasons unrelated to the output impedance, but also to control the output impedance so that it IS very close to 50 ohms (for example in instrumentation, where it may be important).

Cheers,
Tom

Indeed, Keith...nor is it much use, by itself, for computing the source impedance seen looking back into amplifier's output RF connector, at the output end of the network that transforms a (50 ohm, or whatever) load to the impedance seen by the tubes driving that load.

If the tube is operated with cathode (RF) grounded and driven with a stiff voltage source, the impedance looking back into the plate side will be the plate resistance, shunted by stray and tube capacitances; but put a bit of unbypassed cathode resistance in there and the resistive part seen at the plate will be higher, possibly quite a bit higher. Use a triode instead of a pentode, and the plate resistance will be much lower, even though the optimal load presented to the plate may well be quite similar to the optimal load presented to a tetrode. Run the tube grounded-grid and the impedance seen looking back into the plate will be much higher than if it's run grounded-cathode.

I think it helps to understand that the "optimal" load presented to the tube depends on what you want to accomplish: you want a reasonable amount of RF output power with reasonable efficiency and tube operating conditions that will yield good tube life (normally, in our circles). If it's supposed to be a linear amplifier, you want to keep (intermodulation) distortion products below some level. All that has very little to do with the impedance seen by the load looking back into the tube.

Of course, essentially the same situations exist with transistors and FETs as with tubes.

Cheers,
Tom

Thanks to all. Now is a clear statement that my problem is measuring the "inefficiency" of the entire system :)

Only to mention that due to a sort of "quiet life way" with the neighbors, my home setup is a ATU CG-3000 feeding 9,5 meters height monopole with about 40 random lenght radials (from 5 to 20 meters of lenght) and electrically connectet to 200 square meters of chicken fence, with real chickens inside :) perform quite well on 80, from 40 to 12 meters is probably the best antenna i ever had compared to old dipoles, in 10 maybe it is too close to 1 WL... but work almost all , even in furiouses pile ups.

Now that I annoyed with this info, the conclusion of the OP or the third question if you want: how it is possible that mobile setups with the "motorized" antennas can have a minimum of efficiency in 40 meters ?? What the difference from a variabile motoryzed L and an ATU at the feed point ?? Or i miss something important about the 2 feeding methods ??

TIA,

well, i dug out mathcad that will do the ugly symbolic differentiation for me. the standing wave equation can not satisfy the wave equation derived from maxwell's equations as shown in either 'Fields and Waves in Communications Electronics' section 1.14 or 'Classical Electrodynamics' section 6.4. Both of them come down to the requirement that the second derivative wrt space be proportional to the second derivative wrt time. The proportionality constant is the velocity squared. In order to satisfy this the equation must be a function of the form F(t-x/v), the normal representation is the complex exponential which can be presented in a form like sin(t)cos(x/v)-cos(t)sin(x/v) the simpler standing wave equation sin(kx)sin(wt) has the wrong relationship between space and time and therefor can't be a solution to the wave equation. When i work through the second derivatives and collect terms it results in something like Asin(kx)sin(wt)(k^2-w^2) which makes no sense, even in a dimensional analysis the units don't work.

The easiest explanation though is still the intuitive one, the solution of the wave equation derived from maxwell's equations results in the proportionality constant of 1/c^2 which requires the speed of the wave to be c in the medium where it is evaluated, there is no way to get that from the standing wave equation since it is obviously stationary wrt space.

Thanks David, that's good news. It apparently means that the arguments based on energy not crossing a current node boundary in a standing wave are invalid - since that singular condition violates the boundary conditions for Maxwell's equations. So does the "standing wave energy standing still" argument. Not only does the photonic nature of EM waves require them to travel at the speed of light in the medium, but so does Maxwell's equations.

Such knowledge also has ramifications for the technique of using the current on a standing wave antenna to try to predict the delay through a loading coil. If a Maxwell equation analysis of such a condition yields bogus results, how can simple current phase measurements be trusted? If the component traveling waves associated with a loading coil were used in order to obtain a valid Maxwell equation analysis, I wonder what would be the predicted delay through the coil?

> how much of the power going into the antenna terminals is being radiated
> into free space.

The radiation resistance present at the base of an electrically short, linear, monopole (whip) antenna of various ODs can be calculated rather accurately using equations found in various antenna engineering textbooks

So if the base current entering the whip itself can be measured, and whether or not a loading coil was used at the base to resonate* the antenna system, and regardless of the loss in the r-f ground used by the whip -- then for practical purposes the power radiated by the antenna system will be the product of the square of that base current, and the radiation resistance of the whip.

* However "resonated" antenna systems using a short whip do not have the same radiation performance as those using a naturally resonant 1/4-wave monopole. Resonance just means that the capacitive reactance at the feedpoint of the short whip has been exactly offset by the inductive reactance of a loading coil, which can allow for the most efficient power transfer into the radiator.

However the radiation resistance of the whip is not changed by this process -- it is still very low compared to a naturally resonant 1/4-wave monopole. Therefore the radiation efficiency of such a short, loaded, whip antenna system cannot approach that of a naturally resonant 1/4-wave monopole unless the losses in the loading coil and r-f ground are nearly zero.

Loading coils do not replace the "missing degrees" of an electrically short radiator, as far as its radiation resistance is concerned. The radiation resistance of a whip depends only on the electrical length/ OD of the whip, itself.

Most screwdrivers and bugcatchers are more center-loaded than base loaded. The section of the antenna that supplies a good part of the radiation is the straight section between the feedpoint and the bottom of the loading coil. An ATU driven whip doesn't possess that high-efficiency, high-current section. The highest current sections in an ATU system are inside the ATU - not good for radiation. Everything else being equal, a center-loaded antenna will beat a base-loaded antenna by ~3-5 dB according to mobile shootout results. The radiation resistance for a center-loaded 75m mobile antenna is approximately double that for a base-loaded 75m mobile antenna, i.e. close to double the efficiency.

According to 75m mobile shootout results, an ATU driven whip is ~8 dB down from a base-loaded bugcatcher because the bugcatcher coil radiates and an ATU is usually shielded and often uses powdered iron toroids for the coils.

This is true only if you don't confuse the idealized textbook models with real antennas. But most of us are unfortunately stuck with using the latter. In general, the impedance you calculate with the idealized models doesn't match that of real world antennas. It works pretty well for AM broadcast installations, where the length and large number of radials make the impedance relatively independent of ground characteristics. But this doesn't describe the typical amateur monopole antenna, either ground or mobile mounted.

An approximation to input resistance can be made by adjusting for an abbreviated radial system, but this gets increasingly unreliable as the number of radials decreases. The best readily available modeling program allowing the inclusion of a buried ground system, which uses the same well-established equations as textbooks, is NEC-4. It, however, suffers from a serious shortcoming in doing this calculation -- it assumes that the ground is homogeneous to an infinite depth. Real ground is typically stratified, and skin depth at HF is as much as several tens of feet, so the representation of real ground is very poor. There are many cases where a single "equivalent" value of homogeneous ground doesn't exist which gives the same results as actual measurement. I've made very careful measurements of a simple vertical monopole with various numbers of buried radials whose impedance couldn't be matched with NEC-4 using any ground parameters, and I believe this to be a common occurrence. In no case would I depend on a computer model, let alone an even more simplified textbook model, to predict the resistance of a real monopole having an abbreviated ground system with enough accuracy to reasonably estimate the efficiency.

As a side note, Brown, Lewis, and Epstein's sparse radial results can be matched reasonably well with NEC-4, but it does require a fair amount of ground constant adjustment for various numbers and lengths of radials.

Mobile mounted whip antennas fare even worse relative to simple textbook models. I don't have any experience with comparison of computer models

with actual measurement. Those results should depend on the care with which the model is constructed and the amount of influence the ground has on the impedance.

The AC voltage across the diode is 0.26 mV, not 0.26 V.

> The AC voltage is in phase with the AC current through the capacitor, so
> the AC current source is supplying power to the diode, an amount equal
> to Iac * Vac = 0.1 mA * 0.26 V = 0.026 mW. . .

The power supplied by the AC current source to the diode is 0.1 mA * 0.26 mV = 0.026 uW = 26 nW, not 0.026 mW. This is, of course, also Iac^2 * Rac = (0.1 mA)^2 * 2.6.

Yes, understand *perfectly*. My energy go somewhere, and this "somewhere" is heating some toroid into a shield case or radiate on the air. Conservation law.

Center load i think mean also lower ground loss, IIRC.

And as i understand, a RX shootout of the mobile whip compared with my full size 1/4 wl vertical antenna with the same transceiver, to have a suitable relative dB comparison, can give the best test measure i can do with my actual equipement.

Thanks Cecil an other posters, other suggestions or links to learn more are very appreciated.

For the sake of discussion, below are two pastes from the same NEC model using the demo version of EZNEC v. 5.0 -- which rather well support my earlier post that the radiation resistance (NOT the impedance) of an electrically short monopole is a function of its electrical length, and not the loss resistance of the r-f ground and/or the loading coil.

CASE 1 = Zero loss resistance and reactance in the r-f ground, and zero loss resistance in the loading coil:

EZNEC Demo ver. 5.0

1650 kHz 3 meter monopole 6/4/2010 10:50:57 AM

--------------- SOURCE DATA ---------------

Frequency = 1.65 MHz

Source 1 Voltage = 0.08578 V at 35.09 deg.
Current = 0.4986 A at 0.0 deg.
Impedance = 0.1408 + J 0.09888 ohms
Power = 0.035 watts
SWR (50 ohm system) > 100 (25.17 ohm system) > 100

CASE 2 = Same model as above, except with a total of 25 ohms loss in a loading coil and r-f ground, and no reactance in the r-f ground:

EZNEC Demo ver. 5.0

1650 kHz 3 meter monopole 6/4/2010 10:49:40 AM

--------------- SOURCE DATA ---------------

Frequency = 1.65 MHz

Source 1 Voltage = 0.9386 V at 0.22 deg.
Current = 0.03729 A at 0.0 deg.
Impedance = 25.17 + J 0.09579 ohms
Power = 0.035 watts
SWR (50 ohm system) = 1.987 (25.17 ohm system) =
1.004

EZNEC calculated the radiation resistances of these two cases to be 0.14 ohms and 0.17 ohms, respectively -- fairly close, but not exact. Perhaps Roy could comment on the reason why their agreement using NEC/ EZNEC is not better.

Those wanting a good resource for the measured results for monopoles of less than 1/8 electrical wavelength might try to locate the paper by Carl E. Smith and Earl M. Johnson titled PERFORMANCE OF SHORT ANTENNAS, published in the October, 1947 edition of the Proceedings of the I.R.E.

The equation for the radiation resistance of short antennas given in that paper is independent of the resistive losses in any loading coil or r-f ground system.

This posting is more of an update. I pulled the old W9INN down for inspection and found a crack in the PVC. It was interesting to note the imprint on the top of the center conductor (not a balun) says W2AU; however, it does not look like a W2AU on any web page. It has ground strap running from top to bottom. To make a long story short, the crack in top of the device was easily repaired using PVC cement and it passed all continuity tests. It is back in place and working FB.

definately. another simple condition shows this can't be correct
since current nodes correspond with voltage peaks in the standing wave
pattern, so while energy in the magnetic field is a minimum the energy
in the electric field is a maximum.

this becomes MUCH harder to analyze. the transmission line case is
easy because the equations collapse to a single linear dimension, so
you can write your simple standing wave equation with a single sin(kx)
term. in a solenoid, especially a finite length solenoid, and double
especially because the length may be an appreciable fraction of a
wavelength, there is no such simple representation for the fields.
i'm not even sure what software would provide an adequate model of
something like that... the turns are too close for me to trust nec
based programs with out lots more research, and i'm pretty sure finite
element programs like ansoft/maxwell would not be able to handle the
change in current due to length and radiation. measurement of the

currents in coils like that would also be hard because of the radiated fields and the shielding needed to prevent measurement errors from probe lengths in the field... i would only trust fiber optic sensed probes that were small and self contained, at least that way you would not be distorting the field with probes or trying to cancel out pickup from probe cables coupling to the antenna.

I would figure that getting an accurate ground influence in an antenna design program would have to be a daunting project, indeed.

While installing my bugcatcher, I did a lot of it in stages, noting the positive influence on the results. My thinking at this point is that the make and model, and the size of the vehicle would be critical for the model, and small changes go a long way.

What's more, the more efficient and narrow the antenna, the more effect the changes have. Given that a good setup always involves a lot of custom work like bonding and turning potential radiators like the exhaust system into more bonded area, it is a really tough exercise.

As a point of clarification, Cecil, the bottom loaded bug catcher you
refer to - is it the matching coil or the loading coil? I only knew of
mid-loaded bugcatchers.

I'm going to break with my earlier decision to no longer respond to
this thread in order to respond to Tom, K7ITM.

Tom, as you can see from my earlier posts I agree with your assessment of plate resistance, Rp, in that it is the partial derivative of the Ep/Ip relationship. Therefore, while Rp is definitely a factor in determining the value of load resistance RL, it is by no means the total source resistance of the RF power amplifier, as others insist.

I'm going to break with my earlier decision to no longer respond to
this thread in order to respond to Tom, K7ITM.

Tom, if you review my earlier posts, you'll find that I agree with you concerning plate resistance Rp as the partial derivative of the Ep/Ip relationship when both the grid and screen voltages are held constant. Although Rp is definitely a factor in determining the value of load resistance RL, it is by no means the total source resistance RL, as others have insisted.

You can use any Insulated wire, Plastic Insulated or Enameled..... Most
use a very thin enameled 22 Gauge or smaller, and may even be wound on a
Ferrite Core to increase the Impedance...

Hello and good day all:

I believe perhaps I am not translating/understanding well your posts, Cecil and David, I post some comments to your consideration.

As I learnt, basic electromagnetic energy propagation Maxwell equations are satisfied by a traveling wave moving in one direction. Also I learnt standing waves in a TL results of two of them traveling in opposite directions (as I understand this is not a questioned point in this newsgroup), but SW equation it is not a Maxwell eq. solution but a mathematical result of interference among them. For that reason directly replacing this one in electroamagnetic energy propagation Maxwell diff. eqs to satisfy it, do not work, because SW do not travel anywhere!.
Energy not flowing beyond nodes it is a true, but only for ending nodes!
Could this be what confuses those who think energy do not cross INTERNAL TL nodes?

Electromagnetic waves are energy transport phenomenom, SWs not. We can interpret last ones as a "result of the transport phenomenom" (interference) => Energy is "trapped" in a resonant ideal line, as is "trapped" in a resonant ideal cavity, as light ii is "trapped" in a optical ideal cavity.

Do we see a simple case: If we think in a half wave resonant line we can interpret/describe its internal state as two traveling waves (inside system transport) or with a standing wave dynamic interchange of energy between E and H field without radiation (not transport). In longer line it is the same: we can describe its internal state a two waves traveling between end boundaries (transport) or a sistem (line) located [but not f(x)] energy interchange among magnetic and electric field. (I said not f(x), because nodes and antinodes are "FIELDS (E and H) nodes and antinodes", but not "ENERGY nodes or antinodes" (as we know, where H is 0, E is maximun...)

Seems to me this does not violate any quantum or clasic laws :>)

Jim, k7jeb, once used a standard 75m Texas Bugcatcher coil as a base-loaded whip (no top hat) and entered one of the CA 75m mobile shootouts. He was "only" 3 dB down from similar center-loaded Texas Bugcatchers (no top hat). This fits well with the radiation resistance estimate for the center-loaded bugcatcher being double that of the base-loaded configuration.

Well maybe it is much harder using Maxwell's equations but maybe there is a simple representation. See what you think about this idea. At the following web site is an impedance calculator that will yield the characteristic impedance and velocity factor of a loading coil so the coil can be analyzed the same way as a transmission line. (We also can model the whip using EZNEC and, like a transmission line stub, equate the feedpoint impedance to the impedance of a lossy open-circuit stub.) We know the Z0 of the whip will be a few hundred ohms.

http://hamwaves.com/antennas/inductance.html

The velocity factor of the specified coil can be calculated from the axial propagation factor in radians per meter.

So please assume a frequency of 4 MHz and a typical six inch long bugcatcher loading coil with a Z0 of 3800 ohms and a VF of 0.024. All losses in/from the coil can be lumped together as if they were normal transmission line losses. The electrical length of the coil can be calculated from the physical length and VF. I don't see that it is all that "MUCH harder to analyze" than a transmission line example with the same amount of losses.

A short whip can be fed at any point on the radiator.
In Cecil's case, I assume the coil was a true loading coil,
and not the matching coil. As per his numbers, the base
loaded was quite a bit better than the "tuner" loaded whip,
which was 12 db down from the center loaded bugcatcher.
In general, appx 3/4 the length of the whip from the base
will be the appx best location for the coil.
The higher the coil is, the better the current distribution.
But.. The higher the coil is, the more turns of wire you
need to tune. So there is a trade off of current distribution
vs coil loss due to the extra turns.
You could have the coil at 95% high, and have great
current distribution, but the losses of all the turns required
would eat you for lunch.
So... usually around 3/4 of the way up will be about the
optimum location. 1/2 way up is good, and a good compromise
between current distribution and coil losses.
For a given length whip, Reg Edwards "vertload" program
can be used to calculate the best location for the coil,
and having played with it, and using the real antennas to
compare, I think it is very close.
Also, it jives with the info and graphs used in the ARRL
antenna handbook on that subject.

Hi Walt,

Do you have other Data to replace into your copy of Terman's equation?
I got the impression you were satisfied with his work and his
conclusions. Myself, I would say Terman's are suitable but incomplete
and additional data wouldn't change anything as he presented a classic
case.

Hemenway, Henry, and Caulton go miles beyond merely suggesting that
there are partial derivative forms (you can choose to offer your own
from Terman if you can find them), and they give the full treatment
from soup to nuts in chapters outside of the one I have distributed.

As for the comparison of Rp to RL, yes, it is not complete and in fact
although they closely agree, that is only a first cut. Refinement may
go as far as 10s of percent shifts and with the accumulation of
possible errors, that shift might still resolve to Rp = RL.

However, if Rp (or its distant cousin Rpd) slips in value away from
RL, then the match is going to migrate away from the Conjugate basis Z
match towards some other solution. I cannot see how it could be
otherwise unless there were some undocumented and unmeasurable R (not
real) were to combine to balance the books.

If there's a match, the Data and the numerous counter arguments to you
seem to prefer an image basis Z match. I don't hold much confidence
in that outcome either.

Sorry, I can't tell without seeing the EZNEC description file. If you'll attach the .EZ file to an email message to me, I'll be glad to answer your question. I wasn't able to get a radiation resistance that high at that frequency for a 3 meter vertical of any diameter, so there's something in the model which isn't immediately apparent.

And the same fundamental equations are used by modeling programs. The problem is that interaction between the antenna, an abbreviated ground system, and the Earth can modify the radiation resistance as well as adding loss resistance. You might try modeling a few short verticals with a few radials just above ground, and looking at the gain with various radial systems. You'll find that the gain change doesn't exactly correlate with the feedpoint resistance change when you assume a constant radiation resistance. This isn't a shortcoming of the modeling program, but a real effect. I doubt you'll find much about it in pre-computer age texts, though, because it's probably a very tough, or maybe impossible, manual calculation.

And yet....

It is generally accepted that power = volts times current (P=VI) and
that
power is energy flowing, so if the voltage or current is always 0,
there
must be no energy flowing.

The presence of voltage without current, or current without voltage is
an indication that energy is stored, not that energy is flowing.

So are you really prepared to give up on P=VI so that energy can be
flowing (i.e. there is power) when the voltage or current is zero?

I tend to agree. Wave is an overloaded term and this leads to some of
the confusion. There are some phenomena that transport energy which
have a wavy nature. This does not mean that every thing with a wavy
nature is transporting energy.

In particular, it does not mean that when there is a situation in
which
energy is not being transported (e.g. a zero on a transmission line),
that just because the conditions on the line can be described by
decomposing into two waves going in opposite directions, that these

two waves are carrying energy.

Attempting to do this, and believing that these decomposed waves
actually
represent energy flows leads to having to answer questions like "where
does the reflected energy go"? When I first started lurking in this
group
about a decade and half ago, the 'obvious' answer accepted by many was
that it went in to the final and fried the tube. Many have moved
beyond
this simplicity, but some have not yet moved as far as they need to.

that is just another flaw in the 'standing wave' problem. since they
are not real waves that propagate and move energy the P=VI formula is
not correct. you must take the original traveling waves and study the
power and energy using them, from that you should see the proper
results.

My apologies for being insufficiently precise. Where ever I wrote
P=VI,
please substitute P(t)=V(t)I(t).

That is, the power (i.e. energy flow) at any instant in time is the voltage at that time times the current at that time. If, for all time, the current or voltage is 0, then so is the energy flow.

Consider two equal valued resistors connected in series. Connect one end
of the pair to +12 volts, connect the other end of the pair to -12
volts. The voltage at the center is 0. There is certainly current
flowing. There clearly is power dissipated in the circuit.

>
> The presence of voltage without current, or current without voltage is

The above example has current but no voltage, There are no storage
elements, only resistors.

Inductance and capacitance are storage elements. You might find those in
a model of a transmission line, but not in this example.

Could you please explain why, if the same fundamental equations given in antenna engineering textbooks and I.R.E. papers are used by modeling programs, the results of their use do not always support each other very well?

If it is accepted that the radiation resistance of a short monopole is independent of the loss resistance in the loading coil and r-f ground either alone or together, then what is the basis for the variation in radiation resistance that you report?

BTW, the equations in the Carl Smith paper I referred to earlier in this thread produce a radiation resistance of 0.113 ohms for a 1.65 MHz, 9.84' (3-m) x 0.25" OD, base driven monopole -- which is not _hugely_ different than the values calculated by EZNEC.

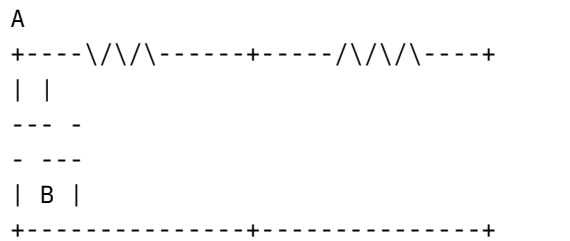
An excellent example. Let's draw it.



Between A and B the voltage is zero. I contend that there is no energy
flowing from the left half of the circuit to the right half. To
demonstrate this, compute the energy contributed by the battery on the
left. It is equal to the energy consumed by the resistor on the left.
Similarly for the battery and resistor on the rigtht. No energy flows
across the plane A-B.

If you still disagree, what is the power flowing across A-B?

I'm not aware of any cases where engineering textbooks and papers disagree with modeling programs. NEC, for example, has been very extensively tested against both theory and measurement. If there are cases where the programs seem to disagree with theory, it's very likely due to careless modeling resulting in a model which isn't the same as the textbook model. Can you cite an example of disagreement between computer model and textbook theory?

> If it is accepted that the radiation resistance of a short monopole is
> independent of the loss resistance in the loading coil and r-f ground
> either alone or together, then what is the basis for the variation in
> radiation resistance that you report?

It is indeed accepted that the radiation resistance of a monopole over a perfect ground of infinite extent has the characteristics you ascribe, and computer models show this independence as they should. (I haven't yet received your model which you feel seems to show differently.) But it's neither true nor "accepted" when the ground system is much less than perfect. The variation is due to interaction between the vertical and ground system, just as the radiation resistance of a VHF ground plane antenna changes as you bend the radials downward. Altering the number, length, depth, and orientation of radials has more of an effect than simply adding loss.

> BTW, the equations in the Carl Smith paper I referred to earlier in
> this thread produce a radiation resistance of 0.113 ohms for a 1.65

> _hugely_ different than the values calculated by EZNEC.

EZNEC gives a result of 0.1095 ohm with 20 segments, converging to around 0.103 ohms with many more segments. Keep in mind that the model source position moves closer to the base as the number of segments increases.

The author's result is good. If you examine the paper carefully, I'm sure you'll find that the author had to make some assumptions and approximations to arrive at his equations -- the most fundamental equations can't be solved in closed form, and many, many papers and several books were written describing various approximations to

calculate something as basic as the input impedance of an arbitrary length dipole. If you do some research, you'll find that the many different approximating methods all give slightly different results. The small disagreement in the cited paper is really a measure of how good his approximations were. Modeling programs have to use numerical methods which are limited by quantization, but they have the advantage of not needing the various approximation methods required for calculation by other means.

Members of this Group should know that in microwave oven are the standing
waves, In the Manual is " when the amount of food is small, sharp points and
sharp edges on metal objects can initiate a corona discharge, a "Saint
Elmo's Fire," which behaves the same as a flame and can set fire to the food
and the oven if allowed to continue for long. Aluminum foil can become a
blow torch!"

Each pulse of the both waves travelling in the opposite direction is
carrying energy. The energy cummulate and can destroy the tube or the oven.

>Many have moved beyond this simplicity, but some have not yet moved as far
>as they need to.

It is important to know that the standing waves are possible only in
compressible medium.
"Maxwell's equations" are for the incompressible electricuty.

right, and this brings up another key error that a detailed look at standing waves points out. go look at one of the animations of standing waves and you will note that in each cycle they go from tall peaks to a flat line and then back to peaks. so if you use p=vi what is the energy in the line when either field is zero from end to end? if you answer zero, then where did it go? it is obviously impossible for the energy in the line to go to zero everywhere every half cycle as that would require propagation faster than light, and some external place for all that energy to dump to. so calculating power that way is worthless with standing waves.

The real die hard standing wave fanatics will look closer and realize they can represent calculate power in each field separately and make it slosh back and forth between electric fields and magnetic fields. That representation may be interesting, but is nothing more than studying the energy stored in a resonant LC circuit. it doesn't go anywhere, it just alternates between the electric and magnetic fields.

> flowing. There clearly is power dissipated in the circuit.

you need to go back to circuits 101 and retake the undergraduate lab
intro where they teach you about measuring current and voltage. your
basic problem statement above is malformed since you can not measure
the voltage 'at the center'. voltages always have to be taken between
two points.

now if you REALLY want to be confused, ignore circuits 101 and draw
any circuit with as many components in it as you want as long as there
is only ONE loop. so connect AC or DC sources, inductors, capacitors,
resistors, around in a circle. start measuring voltage across each
one as you go around the circle and add them up. the result will
ALWAYS be zero. (go read about Kirchhoff's laws, here is one
reference http://www.bowest.com.au/library/theorems.html).

Note that of course these do not apply to transmission line problems
or antennas.

> is the energy in the line when either field is zero from end to end?

We need to carefully understand the meaning of the words. Power is
energy
that is moving; the SI unit is the watt or joule per second. The unit
for energy is the joule.

When the voltage or current is zero everywhere, there is no power,
that
is, no energy is moving. The energy is stored on the line where it
happens
to be. As the voltage or current rises again from zero, the energy is
now moving in the direction opposite to the direction it was moving
before
the line was zero everywhere. At a point where the voltage or current
is
always zero, no energy moves. The energy sloshes back and forth
between
the points in the line that it never crosses.

> it just alternates between the electric and magnetic fields

This is true, but the energy also changes location as it does this,
leading
to energy flow (or power), but the energy does not cross any point
where
the voltage or current is always zero.

When the current everywhere is zero, no energy is flowing, and the
energy
is stored as voltage in the capacitance of the line. And those
voltages are
at maximum and will soon begin to decrease as the energy begins to
flow the

other way.

Similarly, when the voltage is zero everywhere, the energy is stored as
current in the inductance of the line.

...Keith

>yet received your model which you feel seems to show differently.)

The .EZ files for Case 1 and Case 2 were emailed to you this morning.

I had also modeled this short monopole system earlier with basically
the same parameters, using another NEC-2 program (results follow):

NEC-Win Plus+ OUTPUT DATA

C:\Program Files\NEC-WIN\RJF Antenna Files\Case 1.NOU

FREQUENCY= 1.6500E+00 MHZ
WAVELENGTH= 1.8170E+02 METERS

VSWR

Tag: 1, Segment: 1
Input Impedance:
Real(Z) = 0.1127 Imag(Z) = -0.0653

C:\Program Files\NEC-WIN\RJF Antenna Files\Case 2.NOU

FREQUENCY= 1.6500E+00 MHZ
WAVELENGTH= 1.8170E+02 METERS

VSWR

Tag: 1, Segment: 1
Input Impedance:
Real(Z) = 25.1127 Imag(Z) = -0.0653

This NEC study produced identical values of radiation resistance and
input reactance for the same conditions, whereas the EZNEC
calculations, while fairly close, varied from each other. I suppose
this small difference is related to small differences in the
parameters used for the models.

The values of radiation resistance (0.1127 ohms) calculated by NEC-WIN
+ are a very close match to the 0.113 ohms calculated using the
equation in the Carl E. Smith paper.

Below are the two NEC input files from the NEC-WIN+ study, if anybody
wants to load the values into another NEC program to experiment. The
only difference between them is in the load (LD) definition.

Since you include AC sources, the voltages must all be measured at the
same time. Circuits 101 should tell you that.

Keith, you keep leaving out the word "net". If the current on each side of a zero-current point is not zero, all that zero current measurement means is there is equal energy flowing in both directions so there is no *net* energy flow. The fact that Maxwell's equations cannot be used on your condition of interest should be a clue that something is wrong with your concepts and/or logic. You are essentially saying that there is no traffic on the Golden Gate Bridge because the north and south traffic averages out to zero. It is a faulty concept. That zero net traffic keeps on wearing out the roadway.

Your equation is for DC power. The equation for net AC power is
P=V*I*cos(theta). Since, for a pure standing wave, the net voltage is
always 90 degrees out of phase with the net current, the net power at
ALL points is zero, not just at the I=0 point. cos(theta) is ALWAYS
zero for a pure standing wave whether I=0 or not - so your argument is
moot. For a pure standing wave, P = V*I*cos(theta) is ALWAYS zero. I
or V going to zero cannot make it more zero than it already is.

For a pure standing wave, the forward Poynting vector and the
reflected Poynting vector sum to zero AT ALL POINTS.

You left out the word "net" again. Indeed, there is zero *net* energy flow in a pure standing wave. It is technically not a wave because it doesn't transfer energy and momentum. The forward and reflected Poynting vectors can be of any magnitude. They are just equal in magnitude whatever that magnitude might be.

Keith, could you refresh my memory on those instantaneous power equations that you once published. Given a forward wave and a reflected wave, what was your equation for instantaneous power? None of my references consider EM standing wave instantaneous power to be important enough to present a mathematical treatment of the subject.

Just a nit - there is a frequency at which the voltages will begin not
summing to zero. That's when it is time to discard the lumped-circuit
model and go to the distributed network model or Maxwell's equations.

Correction, it must be moving past a point, not just moving laterally from an inductance to a capacitance and back. There is zero net average power anywhere on a wire containing a pure standing wave. Therefore, there is zero net energy flow anywhere on a pure standing wave, not just at the zero current and zero voltage points. The average power in a pure standing wave is zero whether the current or voltage is zero or not. What is important for power is the phase angle between the net current phasor and the net voltage phasor which is always 90 degrees for a pure standing wave. The fact that *power is a scalar with no negative values* and *the average power is zero*, leads one to conclude that instantaneous power is just a mathematical curiosity. Exactly how can the instantaneous power average out to zero average power if there are no negative values of instantaneous power? Seems to me to be one of those numerous "undefined" or "indeterminate" conditions that unfortunately exists in mathematics. When you solve a quadratic equation for a resistance and get plus or minus 100 ohms, do you actually start searching for a -100 ohm resistor? Then why, when you know the average power is zero, do you ask us to go searching for some negative instantaneous power that doesn't exist?

Since power is energy flow *per unit time*, I don't see how power calculated over zero unit time can be anything more than a mathematical curiosity existing in human brains - and unrelated to reality. When one integrates instantaneous standing wave power over one cycle and gets anything except zero, one needs to recognize the error or one's ways.

Hi. ¡Good evening (here) to all..!

> We need to carefully understand the meaning of the words. Power is
> energy that is moving;

Since the energy can be dissipated also transmitted, If we talk in
power FLUX terms (instead power only), I think the issue it would be a
little more understandable because surfaces may have associated
vectors (with "power moving" I believe you are thinking about power
crossing an imaginary surface)

(Note: when I spoke about "unidimensional" nature of a TL space I am pointing to "degrees of freedom" of energy flux circumscribed to its physical path, of course).

For the sake of example we could imaginate a coaxial TL provided with a resistive inner conductor and perfectly conductive outer one. On such TL perhaps we could clearly visualize power flux vector (Poynting vector) "slanted" towards inner conductor to "see" -through simple vectorial decomposition on (over?) the inner wire and pependicular to it directions both => transmission and dissipative nature of phenomenom.
At the same time I believe will be also more ease to account for net power FLUX of opposite directions traveling waves and do not confuse with net power being zero, leading us to the idea of zero energy stored in a ideal resonant TL. Note: In my last mensage I forget to clear that with "resonant line" I was speaking about a section of TL with its ends open or shorted (or a mix) to force a "chemically pure" standing wave :>)

I believe we always must escape from words as "real" or "true" (outside of safe environments such mathematics or digital logic), because "she" easily leads us to the Holy Inquisition dangers :>) Let us the Wave word to be free for jointing with standing, sine, hand, etc, etc. and do we make efforts to understand its conceptual meaning on each context :>)

agreed in general. the initial premise was a couple resistors and
batteries... this is strictly true only for instantaneous voltages
across lumped components.

2140. BNC connectors 75 Ohm versus 50 Ohm?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-06-05 21:49:32 UTC
From: "Geoffrey S. Mendelson" <gsm@cable.mendelson.com>

Source record: 9440

I recently was able to use a crimp on tool for F connectors for RG-6 quad shield coax. To make sure everyone understands, I am in Israel, and RG-6 quad shield coax is cheap and easy to find.

Any other coax is almost impossible to find. Pl-259 connectors, called "UHF" connectors here are rare items. I can get them locally, but I have to special order them and they are expensive. Since I can not see them before I order them, I am as likely to get nickle plated ones with phenolic insulation as I am to get any other kind, and once ordered are not returnable.

BNC to PL-259 adaptors, are easy to get, and can be ordered from a reliable local souce for a relatively small price. The same with N to PL-259.

Looking around at the crimp-on F connectors before I ordered them, I found that you can get crimp on BNC connectors for RG-6 quad shield coax.

Here's my questions, Note when I say crimp-on, I mean the ones that crimp from the rear, like commerical F connectors, not the ones that crimp around the plug. I have never been able to get any of them to "fit right":

1. Can I connect a 75ohm BNC plug (which is a different size) to a 50oHm BNC socket?

2. Are there crimp on 50 ohm BNC plugs which will work with RG6 quad shield? I know there are variations, but most are similar in size.

3. Are there crimp on N connectors that would fit the RG6 quad shield coax? More likely due to the size a crimp on center element that screws into the plug body?

4. Are there crimp on PL-259 connectors?

Thanks in advance,

Geoff.

There is such a thing as a 75 ohm BNC connector, but you are almost
certainly looking at 50 ohm connectors designed for use on 75 ohm cable.
My recollection is that the 75 ohm connectors are incompatible with the
50 ohm connectors, and in some combinations will spread the female inner
part.

>

Yes, see http://www.vk1od.net/transmissionline/RG6/index.htm .
>
> 3. Are there crimp on N connectors that would fit the RG6 quad shield
> coax?

I haven't seen any. I use BNC compression connectors on the RG6, then BNC/N adapters to connect to the antenna N connector. Works fine, all waterproof.

> More likely due to the size a crimp on center element that screws
> into the plug body?
>
> 4. Are there crimp on PL-259 connectors?

Yes. They have most of the disadvantages of the PL-259.

If you are of the view that everything that comes out of China, leave now.

I buy N, BNC, UHF, etc connectors that are of Chinese original that are economical and excellent quality. But... you have to be picky, price is not a good indicator of quality.

There is also a prejudice against RG6. Again, quality varies, and you need to inspect carefully and test product that you might use.

Certainly a standing wave is not a wave that transfers energy.

> Keith, could you refresh my memory on those instantaneous power
> equations that you once published. Given a forward wave and a
> reflected wave, what was your equation for instantaneous power?

Choose a point on the line. Measure the instantaneous voltage and
current at that point. Multiply them together. You have the
instantaneous energy flow at that point and time. Integrate over
a full cycle (assuming a repetitive signal), divide by the period
and you have the average energy flow.

> None
> of my references consider EM standing wave instantaneous power to be
> important enough to present a mathematical treatment of the subject.

Definitely not of interest for standing waves (which everyone agrees
are not really waves), but any decent text will derive
Pavg=Vrms*Irms*cos(theta) for sinusoids by doing exactly the steps
I mention above.

You are welcome.

> from an inductance to a capacitance and back.

Yes, indeed. And so it does. At any point where the voltage or current
is not always 0, energy moves back and forth. This can be readily seen
by computing P(t)=V(t)*I(t) at such a point. P(t) will be a sinusoid
describing the energy flow in the time domain.

> There is zero net
> average power anywhere on a wire containing a pure standing wave.

Yes, but to understand the details, time domain analysis is a great
asset. You need to move away from just averages to understand what
is going on.

> Therefore, there is zero net energy flow anywhere on a pure standing

True, but the instantaneous power is not.

> curiosity.

On the contrary. It is computable and measurable.

> Exactly how can the instantaneous power average out to zero
> average power if there are no negative values of instantaneous power?

There are indeed negative values. These occur when the energy is
flowing
in the other direction, i.e. the direction opposite to that
represented
by positive values of power.

In P(t)=V(t)I(t), when V(t) and I(t) have different signs, P(t) is
negative.

Ahhhhh, but it does. One does not need to search far if one starts
with
a time domain analysis.

> Since power is energy flow *per unit time*, I don't see how power
> calculated over zero unit time can be anything more than a
> mathematical curiosity existing in human brains - and unrelated to
> reality.

Well, this is the basis for calculus...
- instantaneous velocity
- instantaneous acceleration
- instantaneous jerk
- instantaneous voltage
- instantaneous rate of change of voltage
- instantaneous power

All are well understood concepts... and related to reality.

> When one integrates instantaneous standing wave power over
> one cycle and gets anything except zero, one needs to recognize the
> error or one's ways.

In a 'pure standing wave', such integration does result in zero, as
expected. But looking at the time domain details helps reveal the
fine grained behaviour that is obscured when only averages are
considered.

My apologies for being too terse for you. Please use P(t)=V(t)I(t)

> Your equation is for DC power. The equation for net AC power is
> P=V*I*cos(theta).

This simplified form works for sinusoids. It is derived from
P(t)=V(t)I(t),
but loses information since the result is just the average value.

> Since, for a pure standing wave, the net voltage is
> always 90 degrees out of phase with the net current, the net power at

> zero for a pure standing wave whether I=0 or not

Well so it appears when you use the simplified form, but if you use
P(t)=V(t)I(t), that is, do a bit of time domain analysis, one finds
that energy is moving back in forth within the line. It only does
not cross those points where V or I is always 0.

> - so your argument is moot.
> For a pure standing wave, P = V*I*cos(theta) is ALWAYS zero. I
> or V going to zero cannot make it more zero than it already is.

The difference will be easy to see if you analyze in the time domain
rather than just using the averages.

I expect to put some more things on my page
especially the model that I am honing now.
Now I have a 8 inch dia coil about 4 inches high relatively close
wound. Inside is the counter wound coil connected to the other coil to
make a closed circuit. It is placed on a perfect ground in leau of a
reflector. What I have done is balanced the inductance with the
capacitance, as you move around in frequency it will always be close
to resistive because of the balancing I have done.
It takes a while for the program to work from near
near resistance (.01 ohms) and I have now reached 11 ohms for 16.5 dbi
gain where the lower resistance gave me about 30 dbi
The resistance values are wave like as is the variation in gain per

cycle. Field shape so far varies from elliptical to something like the double. zepp. My intention is to plot up to 20 ohms and that will take several times longer than that taken already. The model has about a dozen sections per
winding and I am pretty much limited to 10 segments per section. All very interesting because I am following the idea of canceling all lumped loads in line with Maxwells laws that deals only with distributed loads. Frequency range covered up to now is 685 to 1200Mhz
With this amount of information you can start laughing now well before I put it up
Art

Thanks,

The ad I saw said they were 75 ohm. If they really are 50 ohm connectors
for 75 ohm cable, so much the better. Without buying them, I have no way
to tell, and it's awfully expensive to buy one or two.

Shipping from the US to here runs between $20 (USPS) and $50 (FEDEX/DHL/UPS)
for anything. I was going to buy $10 worth of soldering iron tips from
Farnell, and they wanted a flat rate of $35 to ship them. :-(

Hopefully, it was a "push-on" tool and connector
<http://www.arrisistore.com/digicon/Digicon-F-Connector-Installation-Guide.pdf>
not the piece of junk with the small crimped ring.

>To make sure everyone understands, I am in Israel, and RG-6
>quad shield coax is cheap and easy to find.

There's quality RG-6a/u and junk. On the left coast of the USA, we
have both in copious quantities. I obtain mine directly from a
satellite DTV install company, so the quality is more towards quality
than junk.

>Pl-259 connectors, called
>"UHF" connectors here are rare items.

Be thankful. I find them to be a necessary evil as most ham radios
require them. Meanwhile, commercial radios are moving away from UHF
and toward other connectors, such as Type-N, BNC, TNC, Mini-UHF, and
SMA. However, Comerica base antennas remain UHF or Type-N.

>BNC to PL-259 adaptors, are easy to get, and can be ordered from a reliable
>local souce for a relatively small price. The same with N to PL-259.

That's what I do. Most of my cables are NOT terminated with UHF
connectors. If I need to go to UHF, I use an adapter.

>Looking around at the crimp-on F connectors before I ordered them, I found
>that you can get crimp on BNC connectors for RG-6 quad shield coax.

Yes, they work. I use quite a bit of RG-6a/u and prefer to have
everything terminated by the same connector, which is the CATV
standard F connector. If I need BNC, I use an adapter.

>Here's my questions, Note when I say crimp-on, I mean the ones that crimp
>from the rear, like commerical F connectors, not the ones that crimp
>around the plug. I have never been able to get any of them to "fit right":

Agreed. The good ones are "push on" F connectors.

>1. Can I connect a 75ohm BNC plug (which is a different size) to a
> 50oHm BNC socket?

There are such things as real 75 ohm BNC plugs and jacks. They're
easy to recognize because they lack the PTFE dielectric. The 75 ohm
connectors will mate properly with the 50 ohm connectors. There is
little risk of VSWR problems from using 50 ohm connectors on RG-6a/u.
<http://www.qsl.net/n9zia/wireless/75_ohm_hardline.html>
Basically, any small loss from VSWR is compensated by the lower loss
per meter of RG-6a/u as compared to RG-58a/u. Methinks you're safe
using all 50 ohm connectors.[1]

>2. Are there crimp on 50 ohm BNC plugs which will work with RG6 quad shield?
> I know there are variations, but most are similar in size.

They're nearly identical in dimensions. The 50 ohm variety have some
manner of PTFE dielectric. The 75 ohm variety use a plastic disk and
no dielectric.
<http://www.amphenolconnex.com/products/bnc.asp>
"50 ohm and 75 ohm connectors are intermateable to ensure
non-destructive mating"
The catch is that there's no guarantee that this is true between
different manufacturers. I've blundered across mutations and
variations that are NOT interchangeable.

>3. Are there crimp on N connectors that would fit the RG6 quad shield coax?
> More likely due to the size a crimp on center element that screws into the
> plug body?

Probably, but I wouldn't use one. Just terminate in an F connector,
and use an F to N adapter. The price will probably be the same or
less. However, if you must go direct, any N connector that will fit
RG-59a/u will usually work with RG-6a/u. The problem is that
depending on the number of shields in the RG-6a/u, the outer diameter
will vary, making the diameter of the crimp ring an issue. Doing this
is risky and may result in a non-fitting connector. I would use an
adapter, which will always work.

>4. Are there crimp on PL-259 connectors?

Also probably, but again, methinks you're better off with an F
connector and an adapter.

[1] I just counted 7 assorted coaxial cables going between my roof and
various RF devices in my house. All but one are 75 ohm RG-6a/u. Some
are double shielded, while others are quad shielded. The connectors
are slightly different. All the HF and VHF/UHF antennas use 75 ohm
coax. The one 50 ohm LMR-400 run is for the 900MHz antenna.

Thanks,

Yes, but mine looks more like a nut cracker, however it works the same
way.

> Be thankful. I find them to be a necessary evil as most ham radios

Me too. Since all of the ham radios I have were either brought from the
US in 1996 when I moved here, or even older ones brought here, they use
Pl-259's or in one case an RCA jack (Drake SP-R4) for the antenna.

TV sets still use the Belling-Lee plugs (called PAL connectors in the US)
and so do VCRs. Everything else uses F connectors (cable TV, Satellite TV)
although RF outputs to TV sets have gone the way of the VCR.

DVB is just starting here and the tuners use Belling-Lee connectors. F
to Belling-Lee adaptors are common here, and even in the US, where Radio
Shack sells them.

> That's what I do. Most of my cables are NOT terminated with UHF

OK, So where do you get your adaptors?

> Agreed. The good ones are "push on" F connectors.

I gave up about 10 years ago and used the cheap screw on ones because they
gave me a better fit than the crimp "around" types. The push on ones
are a lot better.

That's not an issue, 900mHz is not a ham band here, and 1.gHz too short
range to consider using. I think there is one 1.2gHz repeater in the country,
and I can't hit the co-located 2m repeater anyway.

Geoff.

just did a check at 3 Ghz. 20 dbi at 5 ohm resistive
so I may not get to 20- ohm resistive So after I get a reasonable
graph I will have to modify the model
to see if I can increase the resistance spam.
Note that the metallic resistance calculated is to gauge losses and is
not the source impeadance

My guess(tm) is that they are less expensive than oddities such as an
N-connector for RG-6a/u. They also have the advantage of being
reusable. When you destroy your coax cable, just unscrew the adapters
and use a new F connector.

I sometimes have to make my own adapters. It's not because the
adapter is unavailable or hard to find. It's because the accumulated
length of the connectors and adapters can get quite long. There are
also mechanical considerations, where an N to SMA adapter will surely
break at the SMA when the heavy cable is bent. For SMA and Mini-UHF
adapters, I sometimes use short pigtails to act as a strain relief.

>OK, So where do you get your adaptors?

It varies. Once a year, I got to one local hamfest and stock up. I
like to see the connectors to make sure they're not junk. I typically
buy about $150 worth every year. Much of it disappears during Field
Day. The problem is that most of this stuff is nickel plated. Nickel
is fine for systems which are not potentially affected by
intermodulation issues. Therefore, I'll use them at home, Field Day,
other hams stations, and my mobile. I won't use them for repeaters,
mountain top sites, and microwave links.
<http://www.amphenolrf.com/simple/PIM%20Paper.pdf>
<http://www.repeater-builder.com/antenna/pdf/andrew-braid-over-foil-imd.pdf>
<http://www.repeater-builder.com/antenna/pdf/recommended-coax-and-connectors-for-iden.pdf>

For repeaters, I use silver plated connectors, when I can get them.
Gold plating is an option, but under the gold is a layer of nickel,
which worries me a little (most of the RF flows on the surface). Tin
plate also works. I buy most of my connectors from RF Industries:
<http://www.rfcoaxconnectors.com>
Their mix is really bizarre. They offer Nickel, Tin, Silver and Gold
plating, but not in every type of connector. For example, F adapters
are available only in Nickel or Gold, while UHF connector are only
available in Nickel and Silver. Trying to avoid dissimilar metals is
difficult.

Other sources are eBay, various online dealers, the local electronics
store:
<http://www.santacruzelectronics.com>
the local cable company, and the local DTV satellite installation
company. The latter are my best sources of RG-6a/u and F connectors.
I once obtained a free bucket full of filthy connectors that someone
had left in the rain. Rather than clean them, they went to me,
instead of the recyclers. There were literally hundreds of F
connectors in the bucket.

If you're working on the HF and VHF bands, you can probably just
solder two connectors together to make an adapter. I have a bunch of
BNC to UHF adapter I made this way. The BNC panel jack fits nicely
into the PL-259 connector. The losses are not signifigant, even at
microwave (2.4GHz) frequencies:
<http://802.11junk.com/jeffl/antennas/connector-loss/>
I've done 8 ft chains of adapters with similar results.

I don't know what to suggest. It sounds like getting someone in
Europe to throw together a collection of connectors for you seems
easier than importing them one at a time.

I assume you are using AOPro, since that is what you have previously stated when asked what you use for analysis. AOPro is an old version of Mininec wrapped in an optimizer with 2D and 3D result presentation. It has none of the current corrections to fix the mathematical mistakes that were made in the original Mininec. Sometimes those mistakes are relevant, sometimes not. In the case of an antenna like you describe, they probably mostly are.

If AOPro say 5 ohms + or - j something, the 5 is the real part of the feedpoint impedance. It is not the loss as you state.

The maximum wire diameters of your model seem to be impractical for use with Mininec where it is not advisable to go beyond .001 wavelengths from what I'm able to determine. Based on that assumption I get a maximum usable wire gauge for 685MHz of 25, and for 1200MHz 30. At 3000 it's a number not even on the AWG table I have -38. So to model this antenna at 3000MHz you should use 38 AWG or smaller wire for any chance of accurate results.

You also stated that it is close spaced but gave no numbers, so I can't comment on that. But I have a feeling that too may violate the limits of Mininec's calculation engine.

Be careful of what you model and how you model it. Distrust miraculous results not confirmed by other methods.

The guage was not meant to be -38, I missed the spacebar. It should
have read

"not even on the AWG table I have - 38."

It's less important here. It rains about 14 days a year spread over 6
months. It rained for about 10 minutes in April, has looked like, but did
not rain at all in May, and won't do it again until around November 1.

><http://www.santacruzelectronics.com>

I'll look at them too.
>
> I don't know what to suggest. It sounds like getting someone in
> Europe to throw together a collection of connectors for you seems

Actually that's a myth. While I am geographicaly closer, postage from the
US is much cheaper than Europe. The only way shipping becomes cheaper if I
were to load a container full on a ship. Then sending it from a Mediterranean
port would be cheaper.

Sending a single package from the US is cheaper and faster than anywhere
else in the world with the usual, but not always exception of elsewhere
in Israel.

A single envelope, even one containing electronic components takes a week
from a vendor to my door. A small box takes 2-3 and I have to go pick it

up at the post office, even if they are the same cost and weight.

The same with internet access, I can download files from the US at twice the speed from the UK, and 4-5 times that from continental Europe.

Thanks. Interestingly enough, they have F-plugs to N jacks, (i.e. cables
with F plugs on them to connect to a radio with an N jack) but not
F plugs to PL-259(UHF) jacks. :-(

73,

Geoff.

Good day Miguel,

I do not disagree with anything you have written, but I do think it
is much too early to introduce Poynting vectors and lossy conductors
to the discussion.

Some of the posters to this group have basic misunderstandings of
the behaviour of transmission lines and using Poynting to address

these misunderstandings is like trying to use quantum mechanics to address misunderstandings of Newton’s third law. And it will be just as unsuccessful.

The basic misunderstanding is believing that a reflected wave necessarily and always transports energy. Rather than using basic circuit theory to demonstrate that this assumption is incorrect, these posters introduce Poynting, optics and photons to reinforce their beliefs. Believing that a reflected wave necessarily transports energy then begs the question ‘where does this energy go?’. At one time it was a commonly held belief that this reflected ‘energy’ entered the transmitter and fried the final. This notion has generally disappeared, but has been replaced by faulty concepts attempting to explain how the reflected ‘energy’ is re-reflected so that is does not enter the transmitter. And all this effort is expended because of a misunderstanding of the nature of reflected ‘energy’.

Until these basic behaviours are properly understood, optics, photons and Poynting merely assist with obfuscation.

...Keith

On Jun 5, 6:28 pm, Keith Dysart <keith.dys...@gmail.com> wrote:
> There are indeed negative values. These occur when the energy is
> flowing in the other direction, ...

Let's take a close look at the illusion that you are seeing and not comprehending. Observe a snapshot of the instantaneous power envelope of a traveling wave. It is a sinusoidal envelope with peak instantaneous power levels and zero instantaneous power levels. When it is traveling in the forward direction we consider that to be positive power. When it is traveling in the reverse direction, we consider that to be negative power. It is only a directional *convention* not proof that negative power exists. The only waves that can exist as waves on a transmission line are traveling waves.

Since the forward wave and reverse wave do not interact while Z0 remains constant, they have zero effect on each other and we can just simply algebraically add the two instantaneous powers to obtain the net instantaneous power. Thus, when the instantaneous power in the forward wave is a greater magnitude than the instantaneous power in the reverse wave, the net instantaneous power is positive. When the instantaneous power in the forward wave is a lesser magnitude than the instantaneous power in the reverse wave, the net instantaneous power is negative. At the point where they are equal, the net instantaneous power is zero. This is the illusion, based on net instantaneous power, that you are observing. Please note that net instantaneous power is an oxymoron. Is it net or is it instantaneous? How can it be both?

All you are observing is that sometimes the instantaneous power in the forward traveling wave is more, less, or equal to the instantaneous power in the reverse traveling wave which causes the net instantaneous Poynting vector direction to alternate. But it is all a moot point because photons cannot perform the feats of magic that you are ascribing to them. You are simply being fooled by an illusion based on the misguided algebraic addition of two separate and distinct instantaneous powers that you believe are interacting but while Z0 remains constant, they are not interacting in any way and it is impossible for the photons to change direction without a physical cause. Your mashed-potatoes version of energy doesn't even obey Maxwell's equations. Why do you think the concept can possibly be meaningful?

In "Optics", Hecht says instantaneous power is "of limited utility." You seem to have discovered that limit, stepped over it, and stepped in it. :-)

Note that P(t)=V(t)I(t) is just Pfor(t) - Pref(t) which loses
information when the subtraction is performed and is not important in
any meaningful way. If, as you say, loss of information is to be
avoided, you should be using Pfor(t) and Pref(t) instead of net P(t).

Translation: I object to anything, including technical references and
laws of physics, that shoots my argument down. :-)

> The basic misunderstanding is believing that a reflected wave
> necessarily and always transports energy.

Please define "transport". An EM wave cannot exist without ExH energy.
If the energy associated with an EM reflected wave is equal to zero,
then the reflected wave cannot be measured and doesn't exist. But we
know that reflected waves do exist just by looking in a mirror -
causing the reflected photonic energy to be incident upon our retinas.
All of the transported energy in the reflected wave in a transmission
line is recovered during the transient state immediately following key
down. Tracking reflected energy from beginning to end result is not
difficult - optical physicists have been doing it for decades. But,
unlike your ideas, their results do not require the violation of the
laws of physics.

Basic question (at least for me) for a very poor antenna matching :
-100 w reach the antenna and 50 w are radiated.
- 50 w are "reflected", what is their fate ?
Are they definitely lost for radiation and just heat the line, the final....

> JC

Hello,

If the source has a linear 50 Ohms output impedance (assuming 50 Ohm cable, no loss), all power will go back into the source. Partly in the form of heat, partly in the form of power saving. However a PA is not a 50 Ohms source, so what happens may vary.

It is very likely that some reverse power reflects back to the antenna (as the transmitter is not a source with 50 Ohms output impedance). So the reading on an instrument that measures true forward power is the sum of the real incident power plus the reflected power from the transmitter towards the antenna. Changing the load may result in a reduction or increase of total forward power. In case of a real 50 Ohms source, the forward power will not change, no matter the load.

The bad match seen from the transmitter may result in a reduction of DC input power (input current reduces), but may also result in an increase of DC input power.

So when you have reverse power reading of 50W, you cannot just say that the PA has to dissipate an extra 50W, it can be more, less and even negative. The negative case is when the input power reduces significantly and the active element has to dissipate less (with respect to the best match condition). In particular high efficiency amplifiers (where the active devices are used as switches), show strong variation in supply current versus load change. Under certain load conditions such amplifiers may show a strong decrease in efficiency resulting in high relative increase of device dissipation.

> 50oHm BNC socket?

The short answer is yes ! A 75 ohm BNC plug is identical to a 50 ohm
one, save that the male pin in a 75 ohm plug is smaller in diameter.
The other way round, a 50 ohm BNC plug will damage a 75 ohm BNC socket.

> 2. Are there crimp on 50 ohm BNC plugs which will work with RG6 quad

Yes. But you have to be careful to get the right sleeve size and
fitting them is not straightforward.

What happens to the 50 joules/second of reflected energy depends upon the phasing between the source wave and the reflected wave at the source impedance. What most amateurs don't understand is there are two mechanisms that can redistribute reflected energy back toward the antenna. Those mechanisms are a re-reflection based on the physical reflection coefficient (what RF engineers understand) and wave interaction resulting in constructive/destructive interference (what most RF engineers don't seem to understand) because, unlike optical physicists, have not been forced to follow the energy flow.

If the reflected wave arrives 180 degrees out of phase with the source wave, the two waves undergo destructive interference and all of the reflected power is redistributed as constructive interference energy back toward the antenna. This is what happens at the Z0-match established at the input of an antenna tuner.

Thus your conditions of 100w forward power and 50w reflected power could be accomplished with a 50w matched source.

If the reflected wave arrives 90 degrees out of phase with the source wave, there is zero interference and the reflected power is dissipated in the source resistor (in a source with a source resistor).

If the reflected wave arrives in phase with the source wave, all of the reflected power and more than 1/2 of the source power can be dissipated in the source resistor.

Such knowledge is old hat for optical physicists who don't have the luxury of measuring voltages in light waves. They rely on a power density (irradiance) equation.

Ptot = P1 + P2 + 2*SQRT(P1*P2)*cos(A)

where A is the phase angle between the electric fields of two waves. The last term is called the "interference term" and that value is what most amateurs are missing in their energy analysis. If the sign of the interference term is negative, the interference is destructive. If the sign of the interference term is positive, the interference is constructive.

Hi Wimpie,

You say this like others, with the air of "knowing." However, when I
ask in response of those who "know" what the PA is NOT, what IS it?

Give me the Z value of your transmitter. Specify all initial
conditions.

We have had lengthy correspondence with Walt Maxwell's very rigorously
measured Kenwood TS830s that demonstrates a Z of 50 Ohms, or nearly
that as is practicable (say +/- 20%); and yet your voice was missing
from this discussion with evidence to the contrary.

as in the other thread, what is the mechanism of that 'interaction'
between waves? i contend there can be no 'interaction' between
forward and reflected waves if the device is linear. so in an ideal
case of a voltage or current source and ideal source resistance there
is no interaction, it is reflected by and/or absorbed in the source
depending on the impedance of the line and source. if the source is
not linear then you would have to calculate the effect of the sum of
the voltages or currents at the source to determine the effect.

The important point that I put forward is that the program is based
around Maxwells formula. In the engineering world this is factual. If
something deviates from Maxwells laws you cannot say 'don't go there'
and you cannot overthrow what the program provides and at the same
time when it is in accordance with Maxwells laws. To follow that path
is to over throw Maxwell to reinforce your own will. That is not
science.
This approach overthrows fact for success in favor of the present
approach on this group that is based on perceived probabilities that
all other competing theories are based upon.
I continue to use my program and let all the chips fall where they
may. So far, and I have a long way to go, is that skin depth minimises
as current flow
moves out of the metallic member and closer to encapsulating particles
provided by the Gaussian equation. There is no reason to put a halt to
this work until it is proven that the program deviates from Maxwells
equations and thus is fraudulent.
I and nobody else, has pointed at any specific point of my work that
specifically states that my approach is in error based on known
boundary rules and classical physics. All assaults have been based
purely on opinion, mostly in a derogatory way to preserve resistance
to change rather than the path of better understanding.

oh please put an end to it... i will tell you outright that the program deviates from maxwell's equations! at very small or very large extremes it deviates quite a lot! and that is of course why all your results that you let it optimize too far are garbage, you are not conforming with maxwell.

> one, save that the male pin in a 75 ohm plug is smaller in diameter.
> The other way round, a 50 ohm BNC plug will damage a 75 ohm BNC socket.

Sorry. Not so. This is one of the most common urban myths in RF
engineering. The pin diameters of BNCs are identical between 50 and 75R.
(Measure them !!)

The 50R and 75R connectors are mechanically compatible in BOTH
directions. Don't take my word for it - check Amphenol's specifications:
"Two distinct types of 75ohm BNCs are available, and both mate with each
other and with 50ohm BNCs. "

I've been using 75R and 50R interchangeably for about thirty years, and
I've had NO mating damage problems. (Mismatches don't worry me - HF
only).

Note - type N and type C connectors WILL be damaged if you try to mix
75R and 50R varieties. I suspect this is the source of the BNC myth.

Also - some Chinese made BNCs are so badly made that they will damage
other connectors - but this is a manufacturing tolerance issue.

2173. Modelling with AO pro

Years ago I pointed out that extending the boundary laws on the
Gaussian law of statics.becoming the same as Maxwells laws pointed out
the presence of particles beyond doubt. All engineers and the
following chatters went along that this was false. This because there
was no mention of this in any book. It took a couple of years that
Richard came upon an utterance by Feyman that pointed that the path I
took was not fraudulent and at last it was written in a book. So years
past before Feymans writings was more widely known and this group
finally changed its approach based only on what is written and not the
path taken to show the presence of particles. No doubt that all
opposed changes to the books and thus lost all their credability with
respect to the understanding of radiation.
Now we have the attack on a computer program and alsothe total
accuracy of Maxwells equationand science itself. Boundary rules are
only good for a single unknown which is why Maxwell was successful.
All programs on antennas use the idea of two resistances, radiation
and metallic. With this they made an ASSUMPTION, and that was skin
depth was a constant which allowed the removal of one unknown leaving
the last unknown to equal what it takes for all factors must equal
zero per Newtons laws.
The program was accepted even tho it didn't result in total facts and
was disregarded by the addition of various don't go there. Fortunately
they left the program as representing Maxwells equation
and did not tweak it to make it what they wanted it to be.Fortunately
they did not tinker with the program to make it a constant
and its integrity was adhered to.

Facts
Use of Gaussian law shows the presence of particles.

Use of the above shows that skin depth of current flow is not a
constant.

Use of the above produces arrays where everything is in equilibrium
required by the natural laws of physics.

Use of the above provides reactiion to the gravity and rotation of the
earth when subjected to boundary rules.

Use of the above shows elevation and accelleration of particles with
radiation which Maxwell called displacement current
because of the units presented.

Present progress shows a "wave" effect on
radiation such as "
packets" which reflect the tank circuit upon which radiation is based.

LIKE ALL NEW VENTURES IN SCIENCE
it is not written in the books until point by point it is accepted by its peers and I will carry on based on my own thinking until all pieces mesh together in the same way they have upto now, so that those with credibility outside this forum can accept my approach ,or point out areas where there is doubts based on the basis of science

The group has shown that when classical
physics are overuled by the consideration of probabilities the result always end in auguments mainly based around interpretations.
For myself I am following classical rules based on the idea that Maxwells equations as well as the AO pro
program is based on fact without any added changes.

Thats what I said... :-(

> Sorry. Not so. This is one of the most common urban myths in RF
> engineering. The pin diameters of BNCs are identical between 50 and
> 75R. (Measure them !!)

I did... :-(

> The 50R and 75R connectors are mechanically compatible in BOTH
> directions. Don't take my word for it - check Amphenol's
> specifications: "Two distinct types of 75ohm BNCs are available, and
> both mate with each other and with 50ohm BNCs. "

I did check that documentation... :-(

> I've been using 75R and 50R interchangeably for about thirty years,
> and I've had NO mating damage problems. (Mismatches don't worry me -
> HF only).

I've probably used them for nearer 50 years, and had to replace damaged
sockets because the bifurcated female pin had one side broken off. I
am aware that some of the early plugs didn't have solidly captive pins
and could move forward and cause damage. Greenpar package the
plugs/sockets clearly marked 50 or 75 ohm. In all that time I've never
bothered to check the specifications until now.

> Note - type N and type C connectors WILL be damaged if you try to mix
> 75R and 50R varieties. I suspect this is the source of the BNC myth.

Having taken your words and accept that I'm wrong, I can only agree that
you're right and it is a myth.

Thanks for the insight.

In the past you have insisted that only average powers were relevent.
Does this mean you are ready to look at power (i.e. energy flow) in
the
time domain?

If so, you might appreciate
http://sites.google.com/site/keithdysart/radio6.

You do seem to mention looking in the mirror quite frequently, as if
it
had something to do with understanding the behaviour of a
transmission
line.

> causing the reflected photonic energy to be incident upon our retinas.

My main idea is basic electricity. If the voltage or current is
always 0, so is the power. This does not violate any physics of which
I am aware.

There is no mixing as in multiplication of waveforms. Perhaps I can offer a simple analogy. Instead of two AC waveforms (forward and reflected), use a DC equivalent. Start with two DIFFERENT batteries. Connect the two negative ends together and declare that to be ground. Connect a resistor between the positive terminals. The two voltages most certainly "interact" across the resistor, resulting in the current and power being proportional to the difference between the two battery voltages. Nothing in this crude example is non-linear, so there's no need for mixing in order to get interaction.

Similarly, the coax cable acts much in the same way. The two batteries are replaced by the incident and reflected signals. At any time, or position on the transmission line, the model can be frozen and the instantaneous voltages and currents be calculated.

>if the source is
>not linear then you would have to calculate the effect of the sum of

If the source (or load) is non-linear, then the waveforms seen on the transmission line will be distorted. This is unlikely because we usually don't install diodes in antennas, or build HF amplifiers with substantial non-linearities (i.e. distortion).

yes, that is my opinion as a professional software developer who has written simulation programs that model lightning on high voltage power lines, on towers, and in ground conductors. And also as a user of AO from many years ago... that program is prone to optimizing into unrealizable and obviously incorrect results, often first seen as rapid changes in currents and gain values. so if you really want to continue, have fun, we all get a good laugh out of your naivety and attempts to explain it with your own version of physics.

Ahhh. I see part of your problem. You are thinking envelopes.

You need to change your point of view to be a particular point on the
line.
At this point, there is a function that describes the voltage: V(t).
It
may or may not be a sinusoid. There is a function for the current:
I(t).
And from these can trivialy be derived a function for power:
P(t)=V(t)I(t).

When I clip my instantaneous voltmeter across a line and measure 0 for
all time, I can confidently say that no energy is flowing, for there
is
not. I am curious as to what you would answer?

> In "Optics", Hecht says instantaneous power is "of limited utility."
> You seem to have discovered that limit, stepped over it, and stepped
> in it. :-)

Well, Hecht may have his limitations when dealing with Optics, but
there
is no reason to expect these same limitations to apply to circuit
analysis.

it is very misleading to try to make a lumped circuit analogy out of a
transmission line problem. the first step in any circuits 101 course
would be to simplify the two batteries into one then solve for the
single simple current across the resistor... no waves, no back and
forth, no interaction between batteries, just a single current and
voltage.

>
> Similarly, the coax cable acts much in the same way. The two

> and the instantaneous voltages and currents be calculated.

they can be, but what does it prove? i want to freeze it just as the
first wave gets to the load, there is no reflected wave yet, so what
good is that? in order to use our common equations there are many
unstated but necessary assumptions. the most restrictive of which is
that we normally only solve for the sinusoidal steady state waves...
this requires that a long time(in terms of the length of the line) has
passed since the source was energized, that it is a single frequency
pure sine wave, and that nothing is changing in time in the load or
line characteristics. given all that there is no need for
instantaneous values, sure they can be calculated or measured, but
they are of no use in most cases.

and obviously if either one is non-linear then all the simple
equations can be abandoned and a more complete analysis must be done.

> JC

I assume that your numbers were obtained using a directional
wattmeter,
that is, forward power is 100W, 50W are reflected and by subtraction,
it is computed that 50W enter the antenna, some of which is dissipated
in the antenna losses and some of which is radiated.

The 100W forward and 50W reflected have no relation to actual powers
but
are simply values that are constructed so that when they are
subtracted
the result is the average power flowing towards the load.

From these numbers alone it is impossible to decide whether the system
is operating as it should or to compute where the losses might be, or
whether there are any losses at all. With an appropriate antenna tuner
it is entirely possible that the transmitter is delivering its design
output of 50W to the line and all of this energy is reaching the
antenna and being radiated.

Thus the whole question of "where does the reflected power go?", is
rather misleading.

Looks like I should step in here, as the answer to this question is
the main theme in the book Reflections--Transmission Lines and
Antennas, the first edition published in 1990, the second in 2001, and
the third in just this past month of May, released at Dayton.

The notion that ANY reflected power enters the source, such as an RF power amp using tubes and a pi-network, is FALSE!!! The output source resistance of these amps is non-dissipative, and totally re-reflects all reflected power from a mismatched antenna. The same is true when using an antenna tuner. When correctly adjusted the antenna tuner totally reflects all reflected power, resulting in a conjugate match at the antenna-coax mismatch, canceling all reactances in the system to zero, thus tuning the non-resonant antenna to resonance. This action if fundamental, and has been a misunderstood myth for centuries.

For proof of the above statements I invite you to read Chapter 23 of Reflections, which you can find on my web page at www.w2du.com. Click on 'Read Chapters from Reflections 2' and then click on Chapter 23.

In addition, Chapter 19 gives more insight, and the addition to Chapter 19 can be found by clicking on 'Preview Chapters from Reflections 3'. The addition shows measured data proving that the output source impedance of the RF amp is the conjugate of the complex load impedance when the pi-network is adjusted to deliver all the available power at a given level of grid drive.

Furthermore, a completely revised edition of Chapter 23 and the total Chapter 19 appear in Reflections 3, which is now available from CQ Magazine.

Forgot to mention that the output of the RF power amp is LINEAR, even
though the input is non-linear. The reason is that the the pi-network
tank circuit is not only an impedance transformer, it's an energy-
storage device that isolates the output from the input. The linearity
of the output is indicated by the sinusoidal shape of the output wave,
and that the voltage and current are in phase when the load impedance
is resistive.

I've responded, explaining the apparent error. Basically, the models included wire loss which caused the base resistance to include some loss in addition to the radiation resistance. The models also included a loading inductor which wasn't at the base. This alters the current distribution relative to an unloaded or base loaded vertical, resulting in an a change in radiation resistance as observed at the base.

The reason that adding 25 ohms of resistance resulted in not exactly 25 ohms of increased base resistance is that part of that resistance was added at the loading coil which wasn't at the base. Impedances added anywhere except at the base will be transformed in value when observed at the base, because the current at the point where the impedance is placed is different than the current at the base. This is why, for example, a center loading coil must have more inductance than a base loading coil to effect the same change in reactance at the base.

There was nothing wrong with the models, but they don't represent the classic simplified antenna analyzed in the paper. They were easily modified to do so.

Well, if you use "basically the same parameters" you'll get "basically" the same results. But if you want exactly the same results you'll have to take more care to use exactly the same parameters.

This model contains no wire loss, and the loading coil is placed at the same segment as the source. Because it differs in these ways from the EZNEC model, you should expect to get different results, as indeed happened. Various implementations of NEC-2 should always give very nearly the same results for the same model. In virtually all cases, as this one, where they didn't seem to, it was because the models were different.

Hello Richard,

Try the following experiment:

Measure the forward power of your PA at a convenient load. Use a
directional coupler for that, not a voltage meter calibrated for
power. The "SET" or "CAL" position of a VSWR meter can be used as
forward power indicator.

Now make some mismatch (for example VSWR=2 at different phase) and
read the forward power. Did it change? If so, the output impedance is
no (longer) 50 Ohms. If possible, disable automatic protection to
avoid changing drive level. I don't know the value for my FT7B, but I
know forward power changes with load variations (as I use it as
"measuring instrument" sometimes).

Virtually all power amplifiers I designed do not have a large signal
output impedance of 50 ohms under significant load change. For some I
measured it because of a discussion on this between colleges.

Measuring method used: change in resistive load, from voltage change
you can calculate the current change, hence the output impedance. One
note, except two, all where solid state.

All high efficiency designs (class E, D) that I did have output impedance far from the expected load impedance. With "far" I mean > factor 2 or < factor 0.5. I did not measure that (as it is not important in virtually all cases), but know it from the overload simulation/measurement and I did the design myself.

The reason for not being 50 Ohms (after matching) is that when you change the load, the active device will go into voltage or current saturation. This is not a hard process, so for small load variation (low VSWR values), forward power will not change much. I think this is especially true for vacuum triode PA where you have significant tube-internal feedback. For large variation (for example VSWR = 2.5, reflected power 18%), you will notice change in forward power for most power amplifiers.

High efficiency CW amplifiers use saturated switches (for example half, full bridge or push-pull), so behave (seen at the active device) as a voltage source. Depending on the total phase shift of the filter sections this may convert to a current source behavior (seen at the output). I had to spent much time to avoid destruction of some circuits in case of mismatch.

If you can drop me a link to the discussion of the TS830s, I would appreciate that.

You need to get a grip. All I did was point out that you may be exceeding the limits of the program you use.

Take your meds.

Hello Richard,

Walt did respond and did a solid statement regarding the amplifier
with matching section to obtain maximum output (so I know the
conditions) This is the point where the tube/transistor is at the
edge of current/voltage saturation.

At that operating point the output impedance is 50 Ohms (for small
load variations). When you change the load significantly (or change
drive level), current or voltage saturation will dominate, hence the
output impedance is no longer 50 Ohms. This is also the reason that
PA intermodulation may occur in close spaced transmitters where some
power from transmitter A enters the amplifier of transmitter B and
vice versa. This also proves that there is no linear 50 Ohms output
impedance.

Best regards,

Wim

That was the old or original style of the W2AU center insulator. You could get with or without a balun inside. The strap was to provide a way to ground the shield of the coax for lighting protection via the hanging eyelet. I remember them from the seventies as a common connection method.

No the size of the center conductor pin is different between 75 and 50
ohm connectors and will either make bad contact or damage the socket.

>
> 2. Are there crimp on 50 ohm BNC plugs which will work with RG6 quad shield?
> I know there are variations, but most are similar in size.

I don't think so, as there are large differences in the diameter of the
2 kinds of coax, both the diameter of the center conductor and the
outside diameter of the coax.
>
> 3. Are there crimp on N connectors that would fit the RG6 quad shield coax?

I've never seen any and can't think of any commercial reason that anyone
would make one.
>
> 4. Are there crimp on PL-259 connectors?

Yes, I use them all the time. I like them much better than the solder on type. Most need the center pin soldered but the crimp connection to the shield is much easier and better done than when soldered
>
> Thanks in advance,
>
> Geoff.
>

It's my experience that Teflon insulated PL259's are inferior to the phenolic insulation type. The PL259 is a non constant impedance connector that gains no benefit from Teflon insulation as to impedance. The ability of Teflon to hold the center pin in placed is greatly inferior to phenolic. One of the advertised benefits of Teflon is to withstand more heat, true but by the time the connector is heated enough to hurt the phenolic, the coax your trying to install is melted way. Nickel is harder to solder to than silver but the real problem with cheap PL259s is the inside diameter of the area with holes your supposed to solder through. I've measured a few and found them to uniformly to have a too big of an inside diameter. This means there is a larger gap between the metal of the connector and the shield than should be. This gap is hard to impossible to fill with solder and makes for poor heat transfer to the braid of the shield. Finding good connectors is much harder than it used to be as most high-end equipment manufacture are not using PL259s anymore and what hams can get are largely junk I'm afraid. I've seen on ham equipment SO239, the jack half, ones that were molded metal instead of machined brass. Those are hard to thread on a plug onto and are of a soft pot metal that cracks or binds.
